The National Health Conference and the Future of Public Health *

ARTHUR J. ALTMAYER

*Member, Interdepartmental Committee to Coördinate Health and
Welfare Activities; Chairman, Social Security Board,
Washington, D. C.*

NO speaker on the special program arranged for this afternoon can be insensible to the honor accorded him. Each of us is aware that the American Public Health Association is meeting this year under unusual circumstances. In the sixty-six years since the founding of this Association, there probably never has been a time when there was such great opportunity and such broad responsibility confronting the public health professions. It is probable that the National Health Conference, held last July, marked a turning point in the health program of the nation. This special meeting provides an occasion to take stock of the proposals suggested at that conference as signposts to the future of public health.

It would be presumptuous for me to address the American Public Health Association in the guise of a public health expert. My rôle is to lay before

you the tentative conclusions reached by a group of technical experts in the federal government and to outline the significance of these findings, as they appear to me and to my colleagues.

Public health has long been recognized as fundamental for the public welfare. But this principle has been honored in the breach as well as in the observance. As our society becomes increasingly complex, health is vitally important to the nation as a whole just as it is vitally important to the individual and the family. As our society changes, health needs change; and health services must adjust themselves accordingly. The essential change which is occurring—and even the most casual observer can see it—is the development of an ever closer focus of the health services upon the economic and social welfare of the family. The National Health Conference recently held in Washington was a logical outcome of this trend. I want to review for you the program discussed at that Conference and to consider briefly its significance to the public health professions.

* Read at a Special Session on Public Health Aspects of Medical Care of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 26, 1938.

THE INTERDEPARTMENTAL COMMITTEE

The background of the National Health Conference is briefly told. Immediately after the passage of the Social Security Act in August, 1935, President Roosevelt recognized that many health and welfare activities then considered to be of an emergency nature were likely to become permanent, and that administration of the newly established responsibilities of government should be effectively coördinated. He therefore created the Interdepartmental Committee to Coördinate Health and Welfare Activities. The chairman of that committee is Josephine Roche, LL.D., formerly Assistant Secretary of the Treasury; the other members are the Under Secretary of Agriculture, the Assistant Secretaries of the Interior and Labor, and myself. This committee undertook to explore its problems through a number of technical committees, one of which is the Technical Committee on Medical Care. This subcommittee is composed of representatives from the U. S. Public Health Service, the U. S. Children's Bureau, and the Social Security Board.

The Technical Committee on Medical Care made extensive studies of the health practices and of the needs of the country. It summarized its findings in a report entitled "The Need for a National Health Program." On February 14, 1938, this report was presented to the Interdepartmental Committee which approved it and submitted it to the President.

The President recognized the urgency of the needs described in the report of the Technical Committee and suggested that the Interdepartmental Committee lay the Technical Committee's report—including its recommendations—before a public conference. Miss Roche called the National Health Conference in Washington in July to analyze the problems and to discuss the recommendations of the Technical Committee. Some

of you attended the Conference; all of you know about it in a general way. I intend, therefore, only to summarize briefly the recommendations made by the Technical Committee at that time, giving special attention in this review to those aspects of the recommendations which are of special concern to you.

TECHNICAL COMMITTEE'S RECOMMENDATIONS

The committee presented five recommendations for discussion—and, at the outset, let me emphasize these were *recommendations* only. No resolutions were passed at the National Health Conference; no program was voted upon. Action will come later, when and if the citizens of this country initiate it through their legislative representatives.

The first recommendation was that the existing federal-state coöperative program for general public health services and for maternal and child health services, both recently strengthened under the Social Security Act, be further extended through enlarged grants-in-aid to the states.

Under this recommendation, the committee first proposed an expansion of general public health services. Prevention must always be regarded as the first step in a health program. Expansion of preventive health services means the strengthening and extension of organized public health services which are furnished primarily in the states and in the local communities. Federal participation in the existing coöperative program, developed under title VI of the Social Security Act; should be increased with a view toward equalizing the public health services throughout the nation by strengthening these services where they are weak. The committee further proposed that increased federal participation be used particularly in promoting an attack on certain important causes of sickness and death for the control of which we already have effective weapons.

It has long been an accepted maxim that public health is purchasable, but it has also long been the practice that we do not really purchase it. If we want effective public health service, we must really want it and must be prepared to pay for it.

The rate at which the program can be developed depends upon many factors, involving the states, the local communities, and voluntary agencies, as well as the federal government. The rate of expansion must be geared to the development of administrative and coöperative organization and to the availability of trained and experienced personnel. The committee's recommendation called for a careful but steady expansion toward a 10 year goal when an adequate program of expanded public health services would require additional expenditures by federal, state, and local governments of about \$200,000,000 a year—that is, about \$1.50 per capita.

The second part of the first recommendation deals with the expansion of special maternal and child health services. The committee proposed an expansion of the federal-state coöperative program already developed under title V of the Social Security Act. The goal is to assure to mothers and children of all income groups and in all parts of the United States at least those minimum medical services which are essential to reduce our needlessly high maternal mortality rates and death rates among new-born infants, and to prevent diseases and conditions which occur in childhood and lead to serious disabilities in later life. The committee's recommendation calls for a gradually expanding program and this will cost money. If all that should be undertaken were brought into practice, the program would require, by the 10th year, total additional expenditures of about \$165,000,000 a year or about \$1.25 per capita.

The committee recommended that approximately one-half of these increased funds be provided by the federal government.

Expressed in millions of dollars, the costs involved in this first recommendation seem large—an eventual \$365,000,000 per annum. But when related to the expanding population in the 10 years for which the program is laid out, the total comes to about \$2.75 per person per year.

The second recommendation was concerned with federal grants-in-aid for the construction of needed hospitals and for provision of temporary maintenance grants in the first 3 years after these new hospitals are built, in order to assist the local communities in taking over the responsibility for using and supporting them.

The committee's study showed that we need about 360,000 additional beds—taking into account beds needed in general, tuberculosis, and mental disease hospitals in both rural and urban areas—and that we need at least 500 health and diagnostic centers in areas not readily accessible to hospitals or not sufficiently populated to require or to be able to support fully equipped hospitals. Improvement and modernization of existing facilities is, of course, included. Averaged over a 10 year period, the total annual cost of this program, including both construction and temporary maintenance, is estimated at a little under \$150,000,000, of which about one-half should be met by the federal government.

The committee pointed out, of course, that construction of new hospitals would be an unwise procedure if there were not, at the same time, provision to help meet the costs of hospital care. Otherwise, the new hospitals, as well as many of the existing hospitals, would still be unavailable to the poor and to people with small incomes; the net result would be more empty hospital beds and

continuing inadequate service. The third and fourth recommendations of the committee deal with this problem.

The third recommendation called for federal grants-in-aid to the states to help them meet the costs of a medical care program for recipients of relief or public assistance and for other persons with low incomes who are able to meet the ordinary costs of living but not the extraordinary costs of illness.

The facts brought to the attention of the committee show that the one-third of the population which is in the lower income levels is receiving inadequate general medical services. This applies to more than 20,000,000 persons who are supported by general relief, work relief, old-age assistance, or other forms of public aid; and to about 20,000,000 other persons in families with incomes of \$800 a year or less. These 40,000,000 people are doubly handicapped. They have higher rates of sickness and disablement than prevail among groups with larger incomes, and they have lesser capacities to buy and pay for the services they need. Current provisions for medical services are inadequate to meet their needs. The committee recommended that the federal government assist the states through grants-in-aid to strengthen medical services for these two broad groups of the population.

It is estimated that, on the average, \$10 a year per person in the groups to be aided would be required to meet the minimum needs for essential medical and surgical care, diagnostic services, hospitalization, medicines and appliances, and emergency dentistry. The use of governmental hospitals in communities where they are available is, of course, assumed. The use of non-governmental hospitals, paid for on a proper basis by public funds, is also assumed as a part of this program wherever local conditions make this policy necessary or expedient. Thus, a strengthened program of public medical services for

medically needy persons would help to make use of existing hospital beds, and also of newly constructed hospital beds where the facilities are inadequate, and would help to meet the costs of hospital services for these medically needy persons. This also applies to the use of out-patient clinics and similar facilities.

This part of the program might be begun with the expenditure of \$50,000,000 the first year and gradually expanded until it reaches the estimated level of \$400,000,000 which would be needed to provide minimum care at an average cost of \$10 per person a year to the 40,000,000 medically needy people. The committee recommended that one-half of the total annual cost be met by the federal government.

The fourth recommendation was presented as complementary to the third and called for grants-in-aid to states to enable them to set up a general program of medical care, either by the use of taxation, or by state health insurance programs, or by a combination of the two.

The first three recommendations, you will note, took account of general or special preventive services, hospital construction and modernization, and services for the medically needy. This fourth recommendation turns to the problems of persons who are ordinarily self-supporting. The committee directed attention to the economic burdens created by sickness, especially among low-income groups, and concluded that there is need for measures which will enable people to anticipate and to meet sickness costs on a budget basis.

Without great increase in total national expenditure, the burdens of sickness costs on families and on the public can be greatly reduced through arrangements to distribute these costs among groups of people and over periods of time. The more adequate prevention and care thus made possible would lessen both individual disasters and the

public burdens arising from dependency.

The committee recommended consideration of a comprehensive program designed to increase and improve medical services for the entire population. To finance the program, two sources of funds could be drawn upon: (a) general taxation or special tax assessments, and (b) specific insurance contributions from the potential beneficiaries of an insurance system. The committee recommended consideration of both methods, recognizing that they may be used separately or in combination.

A program of medical care to serve the entire population is an objective to be fully attained only after some years of development. The rôle of the federal government should be principally that of giving financial and technical aid to the states in their development of sound programs through procedures largely of their own choice.

Though this fourth recommendation deals primarily with medical care for self-sustaining persons, the committee recognized that it would be unsound for the states to develop for the self-supporting population medical care programs which are separate and apart from whatever the states might develop for needy persons. Accordingly, the committee proposed that while the fourth recommendation deals primarily with state medical programs for self-supporting persons, a sound state plan should make provision for the care of the needy persons under the same system that is developed for the self-supporting. Accordingly, you will note that this fourth recommendation is broad and absorbs the third recommendation which dealt only with public medical services for the needy and the medically needy.

The fifth recommendation proposed that federal action be taken toward the development of disability compensation—that is, benefit payments to insured workers who are temporarily or perma-

nently disabled. This recommendation contemplates insurance against loss of wages on account of disability.

Under the present social security program, millions of workers may count on some continuance of partial income in lieu of their regular wages when they become unemployed and are able to work.

Under the workmen's compensation laws, most of them are protected against wage loss resulting from accident or injury arising out of employment. But generally they have no protection against wage loss resulting from non-industrial sickness or accident. A limited number of workers do have some such protection through voluntary insurance schemes, commercial or non-profit, but they are a small minority in the total.

There is good reason to believe that insurance against disability can best be treated not by a single insurance system but by two systems closely coördinated. There is, first, the problem of the temporarily disabled worker—the worker who has an acute illness and for whom there is every reason to expect that, after a few weeks or a few months, he will recover and return to work. There is, second, the problem of the permanently disabled worker—the worker who, by reason of crippling or chronic illness, will probably never again be able to enter gainful employment.

Temporary disability compensation, with a substantial waiting period—7, 10, or 14 days, with benefits calculated at 50 per cent of wages for a benefit period of at least 26 weeks, would cost approximately 1 per cent of wages. The cost should probably be divided between employers and workers, though a share of the cost might be carried by general taxation. Such an insurance system would normally be financed on an annual fiscal basis, involving no reserves other than for operating and contingency purposes.

Permanent disability insurance, with

benefits geared to old-age and survivors' benefits, would probably cost 0.2 per cent to 0.3 per cent of wages in the early years, but the cost may be expected to rise in the course of years, the exact costs depending upon the size of the benefits provided and upon numerous other factors. This type of insurance could be established by liberalizing the present federal old-age insurance system.

ENDORSEMENTS OF RECOMMENDATIONS

You will note that these five recommendations present alternative programs to be selected or modified by the states. Except for the proposal to integrate permanent disability (invalidity) insurance with the federal system of old-age insurance, all the recommendations place the federal government in the rôle of giving financial and technical assistance toward programs which are to be operated by the states and the local communities. The recommendations propose, not the building up of a vast federal health machinery, but the strengthening and growth of the existing state and local arrangements through which health and medical services are furnished.

The reports and recommendations were submitted to the members of the National Health Conference, who included both lay and professional persons representing the widely diverse groups who constitute the population of the United States and who are actively concerned with health and welfare. As you know, the national health program submitted to the Conference has been the subject of active study and discussion among many public groups, both lay and professional, since July. Various groups concerned with labor, agriculture, welfare, and health have not only indicated their deep interest in the program, but have given it broad and substantial approval.

The American Medical Association

called a special meeting of its House of Delegates in September to study the recommendations. It is gratifying that this body saw its way clear to endorse the substance of the four recommendations dealing with expansion of public health, maternal and child health services, construction and improvement of hospitals and related facilities where needed, medical care for needy persons, and insurance against disability wage loss. The House of Delegates did not, however, see its way clear to endorse the fourth recommendation, dealing with the development of a general medical care program through taxation or insurance, or a combination of the two.

Though I have referred to the endorsements which the national health program has already received, I would like to place my emphasis otherwise. At this time, the Interdepartmental Committee is more concerned that the national health program should receive careful and critical scrutiny than that it should be endorsed. I cannot emphasize too often that the recommendations were submitted to the National Health Conference as a basis for discussion and not as a blueprint for adoption. We therefore hope that the recommendations will continue to be carefully studied by both lay and professional groups.

PERSONNEL AND ADMINISTRATIVE PROBLEMS

The national health program contemplates developments which would have profound implications for public health administration at all levels of government — national, state, and local — and for voluntary agencies as well. Safeguards are set up, first, in the fact that every element in the recommended program contemplates gradual rather than sudden development, and, second, that every measure closely related to existing health activities proposes operation at the state and local level and is integrated with existing activity.

The recommendations were visualized in terms of a development which might attain its goal in about 10 years. Even such a rate of development might have seemed too rapid a few years ago. Many of you will recall the fears first expressed when the programs to strengthen public health and child and maternal services were being developed in the original design of the Social Security Act. However, the state and local departments of health and the public health professions soon found that the financial aids which became available under titles V and VI of the Social Security Act were quickly absorbed into the existing programs, and only too soon the funds were found to be inadequate. Their inadequacy, I might remind you, was fully foreseen when the Social Security Act was being designed. The appropriations requested had been deliberately reduced below those which our studies had shown to be necessary, so as to avoid a potential shortage of trained personnel. Experience has shown, however, that a gradually expanding program develops its own stimulus for the training and development of the personnel needed.

I do not wish to minimize the problems involved in the development of competent personnel. No doubt this touches on one of the most difficult of all problems involved in the national health program. I am confident, however, that the experience under titles V and VI justifies our belief that a gradually expanding program, such as was recommended by the Technical Committee, will stimulate development of adequate personnel if federal grants-in-aid continue to assist the training of needed personnel. I would also like to point out that personnel can be trained if we have funds and facilities, but they can become experienced only by doing the jobs for which they were trained.

Health services are at many points interlocked with welfare services, and

in the nature of the case this is inevitable. Much thought and attention is being given to the question where the primary responsibility should be placed for those major elements of the recommended program which have both health and welfare aspects. Should such administrative responsibility reside primarily with the health or with the welfare authority? I do not profess to know the answer at this time. It has been suggested, however, that in states where welfare authorities have had no specific responsibility under state law to administer health and medical services for persons with whose care they are otherwise charged, the primary responsibility should be assumed by the health authorities; in other states, where welfare authorities have broad responsibilities for health and medical services according to state law, but where they have had meager funds or none for the discharge of these responsibilities, it is suggested that there also the responsibility should reside with the health agencies. In still other states, where the welfare authority has been actively administering certain health services, it is suggested that such arrangement might continue. These are matters which obviously must be determined by the states rather than by the federal government. We have supposed, however, that federal standards would require that in every case there should be provisions in the state plans for the close and effective coördination of the work of related health and welfare agencies.

THE FUTURE SCOPE OF PUBLIC HEALTH

In a final sense, questions of finances, personnel and administrative responsibilities are secondary. What is the necessary scope of public health service in the future? That—it seems to me—is the basic question. The answer to this question will determine in large measure the part that you, as public

health practitioners, will play in the health program of the future.

Public health practice is as old as society. In its modern form, however, it is a young branch of public administration. The major activities of local, state, and federal health agencies are of surprisingly recent development. Yet the development has been so active that when we find that basic technics are not carried out in a community, we surmise that adequate funds and trained personnel are lacking. Experience shows clearly that the improvement of health services in poor localities may generally be effected by provision of adequate funds. You, the professional public health practitioners, have the knowledge and skills to carry out the tasks which we have come to recognize as public health activities.

While you have been developing preventive technics, the nation has been growing older, more populous, and more complex. Health needs have become highly diversified, and the diversification has been accompanied by other developments of the most profound importance to you. No longer is it possible for you to draw a sharp line between prevention and treatment. As medical knowledge and skill have increased, the public has become more coöperative and more alert to its health needs. The public nowadays wishes to avoid illness and disability that formerly were assumed to be the lot of mankind. They have learned through the efforts of health agencies and from the press, the radio, and other media of communication that a large part of illness which they still suffer is avoidable, that medical care in the early stages of illness frequently prevents the development of serious disabilities. The public knows that the professions possess the knowledge and skills requisite to make this a much more healthful nation than it is at present. With this public understanding of the possibilities inherent in

health service has come a popular demand that there be made available to everyone, regardless of economic status, the services and facilities which now all too frequently are luxuries beyond the reach of those who have small means. The public is no longer satisfied to secure medical care only under the pressure of actual pain and sickness; rather, it wishes to conserve health by avoiding illness, and it wishes to secure health wherever possible by the full use of all the services at the disposal of the professions.

It is because of this awakening of the American people to the possibilities of positive health activities that I foresee the broadening of public health services beyond their present scope. The American Public Health Association, I am fully convinced, is at the beginning of a new era in the field of health services and medical care. I think you are going to have increased opportunities to develop our communities into healthier and happier places in which to live. Indeed, public health work in America has been moving in this direction for a long time, and it has become evident to many of you—as it has to many of us—that you have been but laying the foundations for the national health structure that we hope is to be built in the years ahead.

In all of the development which has occurred, it seems to me that a fundamental trend stands out plainly and clearly. Not long ago—as society measures time—public health practice was concerned very largely with the sanitation of the environment; then its emphasis shifted to the infectious diseases; and then it shifted again to the problems of personal hygiene. In each of these periods, public health practice built upon the accomplishments of the prior periods. Through each of these periods, emphasis was still primarily upon prevention. The line which sepa-

rated prevention from treatment was once sharp, but latterly it has become dull. All recent trends point to the time when this demarcation will be possible only with steadily increasing difficulty. Indeed, it seems to me that the time has already arrived when public health administration must be prepared to discard that old separation *between prevention and cure*.

It is my impression that for at least a decade the public has not understood or appreciated why community responsibility—as expressed through the work of its health department—ended with prevention in those situations when prevention fails to be effective. As society faces the existing need to deal more adequately with sickness, it turns more and more to its public health officers, and it expects them to take on larger burdens and increasing responsibilities. Society looks to the public health officers for more service and on a broader front. Society is compelled to do this because its only alternative is to turn to agencies less equipped, professionally and technically, to deal with health problems.

I would not give you the impression *that I think the official health agencies* should become charged with obligations to provide all the health and medical services which a community needs. What I do have in mind has been said so effectively by others that, even at the risk of trying your patience, I want to read a lengthy quotation which seems to me to offer a sound guide for a developing public health program.

Health officers were once content to deal only with the most urgent sanitary needs of the environment and with the most pressing problems in the control of communicable diseases. In more recent years, it has come to be recognized that the responsibilities of the health department embrace other fields. The modern health officer has an obligation to educate the public in the ways of healthful living, in the prevention of infant and maternal deaths from certain causes, in the postponement of deaths from some causes not

preventable. It is now recognized that his responsibilities go even further. Evidence of many sorts has shown that some of the greatest opportunities to improve the public health involve the early diagnosis of diseases which are at best only partially preventable and which in the past have not been dealt with on a community basis, and the provision in the community of personnel and facilities whereby early diagnosis can be followed by prompt and adequate professional care. The increasing complexity of social forces and their effect upon the health of individuals focuses attention upon diet and nutrition, upon housing, upon opportunities for recreation, and upon social and economic factors generally which exert profound influences upon health. The modern health officer must be concerned not only with community health service as formerly envisaged, but also with the general health of the individual and with the social and economic circumstances of the community in so far as they affect the health of the individual. However, in focusing attention upon the individual, the health department cannot afford to neglect the services to the community as a whole.

Though the modern health officer has wider opportunities than his predecessor, this does not mean that he or the local government must necessarily assume responsibility for providing all the services which come within the field of health interest. It does mean that he has broad responsibility to survey the health conditions in his community, to measure its health needs, to ascertain the extent to which his community is supplied with necessary personnel and facilities, and to participate in the formation of practical plans—appropriate to the community's needs and means—to assure that adequate personnel and institutions are available in the community. On this basis, the health officer becomes the officer of local government chiefly responsible for planning, whether the service is to be administered by the health department or by other agencies, public or private, organized or unorganized, collective or individual.

Some of you may have recognized this quotation. It comes not from some uninformed or ill-advised group. It is not the dream of some academician. It is a statement of policy published under the imprint of your own Committee on Administrative Practice which for many years has guided your Association wisely and skillfully in public health administration. These two paragraphs

which I have just read are taken from the statement of policy which appears in your recently issued *Appraisal Form for Local Health Work*. It seems to me that the aims and objectives of the national health program developed by our Technical Committee on Medical Care can be met wisely and effectively within the framework of the policy laid down by your Standing Committee.

Public health practice in its modern form is a relatively young art. Its vitality is evident, however, not only from its accomplishments of the past, but also by the diversity of the professions which it has come to embrace. You have won and you hold the confidence of the public. The accomplishments of the past, to which you can turn with pride, are notable and significant, and they are greatly appreciated by society. It is not sufficient, however, merely to praise past performances or accomplishments. The accomplishments of the past in health conservation are

secondary to the needs of the present and of the future. Government, which is the instrument of the public will, must, go forward, seeking out ways for those further advances which can be made by dealing with the needs which still prevail. The amount of preventable sickness and disability, the volume of unattended disease, the rate of premature mortality, and the prevalence of individual and social burdens created by sickness are a challenge which we must meet.

The national health program is no finished blueprint; it is only a first sketch. The reports of our Technical Committee are before you for study, discussion, and criticism. The Interdepartmental Committee will be grateful to you, collectively or individually, for the help you can give in designing and developing a still better and more specific program which may guide the nation in its effort to improve the public health.

Attitude of the American Medical Association Toward the National Health Program *

IRVIN ABELL, M.D.

President, American Medical Association, Louisville, Ky.

FOLLOWING the passage of the Social Security Act, the President appointed an Interdepartmental Committee to Coördinate Health and Welfare Activities in order that the full benefits of the federal program under the act's provision may reach with minimum delay and maximum effectiveness the men, women, and children for whose purpose the program was brought into existence. Its chairman, Josephine Roche, LL.D., in a memorable address made to this Association during its 1937 annual meeting, and in a paper read to the House of Delegates of the American Medical Association in June of this year, presented data, statistics, and conclusions assembled by the Technical Committee on Medical Care, a subcommittee of the Interdepartmental Committee. The studies of this subcommittee indicated that the deficiencies of the present health services in the United States fall into four broad categories.

1. Preventive health services for the nation as a whole are grossly insufficient.

2. Hospital and other institutional facilities are inadequate in many communities, especially in rural areas, and financial support for hospital care and for professional services in hospitals is both insufficient and precarious,

especially for services to people who cannot pay the costs of the care they need.

3. One-third of the population, including persons with or without income, is receiving inadequate or no medical service.

4. An even larger fraction of the population suffers from economic burdens created by illness.

At the National Health Conference held in Washington in July at the call of the Interdepartmental Committee to Coördinate Health and Welfare Activities a National Health Program was submitted comprising five recommendations "designed to meet with reasonable adequacy existing deficiencies in the nation's health services." Before reporting the action of the House of Delegates of the American Medical Association on these proposals I beg your indulgence in briefly discussing the principles and policies of the Association relative to a wider distribution of medical care and of its experimentation in this field, indicating both its awareness of the changing needs and of its efforts to meet such needs on an evolutionary basis. The principles and policies adopted in the past have been developed with the single purpose of maintaining the quality and standards of medical care. The American Medical Association has constantly recognized the need for continued expansion of preventive medicine and a wider use of medical

* Read at a Special Session on Public Health Aspects of Medical Care of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 26, 1938.

care. It has, however, at the same time been greatly concerned with the methods of administering both preventive medicine and medical care and with the ultimate effect of various changes on the morale as well as the health of our people. It is a fundamental tenet of the American Medical Association that the poverty of a patient should demand the gratuitous services of a physician. It is also a fundamental tenet of the American Medical Association that it is unprofessional for a physician to dispose of his services under conditions that make it impossible to render adequate service to his patient because to do this is detrimental to the public. Within these fundamental tenets experimentation in new forms of medical practice has not been inhibited. Among the main types of medical care plans now in operation or proposed throughout the United States by the medical profession and other interested agencies the following may be mentioned:

1. State and County Medical Society Plans, of which 152 are operating and 80 proposed. These fall into three main categories—plans to care for the indigent sick, postpayment plans, and prepayment plans to care for the low income groups.

2. Group Hospitalization Plans, of which 68 are operating and 62 proposed, designed to furnish hospital services on a prepayment basis.

3. Hospital Insurance Companies, 54 operating, offer cash benefits for expense due to hospital residence.

4. Flat Rate Plans, 19 operating, whereby an all-inclusive charge is specified for designated services.

5. Industrial Medical Care Plans, of which there are at least two thousand in operation. These are largely of two main types, one providing first aid and emergency care for employees and supervision of plant hygiene and safety conditions, the other providing more extensive medical care for employees, and often for their dependents.

6. Medical and Hospital Benefit Organizations, of which there are at least five hundred whereby funds are accumulated from members through the sale of membership certificates and contracts for the purchase of medical and hospital services.

7. Union Sick Benefit and Fraternal Plans, whereby medical and hospital services are furnished members of a trade union or fraternal order.

8. Group Practice Plans, of which there are more than three hundred, afford arrangements whereby physicians cooperate in practice.

9. Student Health Services, of which there are at least three hundred, which may be compared to industrial health services with particular emphasis on health education.

10. Rural Medical Care Plans, of which there are two main types, one, health associations which guarantee a physician an annual income as an inducement to locate in the community, the other, Farm Security Administration Plans to provide medical service for low income or destitute farm families.

The American Medical Association has never opposed suitable care by municipal, county, state, or other governmental agency for the indigent or those on the borderline of indigency. It has never opposed suitable participation by the government through any of its agencies in preventive medicine, or in any legitimate function of the government in relationship to the care of the sick. The Association has constantly opposed any attempts on the part of the local, county, state, or federal governments to make medical care a political issue. The Association has never opposed the principles of insurance, but it does oppose the political administration and manipulation of the insurance organization and the interposition of any outside agency in the relationship between doctor and patient which is fundamental to good medical care. The principles and policies thus far established do not forbid nor have they ever contemplated any opposition to a well considered, expanded program of medical service when the need for such is established. Neither is there any fundamental principle or policy which in any manner opposes aid to the indigent or medically indigent when such indigency is established. With these principles and policies in mind the American Medical Association convened its legis-

lative body, the House of Delegates, in Chicago in September, inviting to the meeting the secretaries and editors of its component state associations, for the purpose of considering the program submitted by the Interdepartmental Committee at the National Health Conference. At the conclusion of its deliberations, during which full opportunity was afforded the representatives of the 110,000 members of the Association for discussion of the matter at hand, unanimous approval was given to the final report of the Reference Committee of the House. In expressing to you the attitude of the American Medical Association toward the proposed National Health Program, I cannot do better than give you, verbatim, the committee report, which reads as follows:

"Since it is evident that the physicians of this nation, as represented by the members of this House of Delegates convened in special session, favor definite and decisive action now, your committee submits the following for your approval:

"1. Under Recommendation I on Expansion of Public Health Services: (1) Your committee recommends the establishment of a federal department of health with a secretary who shall be a doctor of medicine and a member of the President's Cabinet. (2) The general principles outlined by the Technical Committee for the Expansion of Public Health and Maternal and Child Health Services are approved and the American Medical Association definitely seeks to coöperate in developing efficient and economical ways and means of putting into effect this recommendation. (3) Any expenditures made for the expansion of public health and maternal and child health services should not include the treatment of disease except so far as this cannot be successfully accomplished through the private practitioner.

"2. Under Recommendation II on

Expansion of Hospital Facilities: Your committee favors the expansion of general hospital facilities where need exists. The hospital situation would indicate that there is at present greater need for the use of existing hospital facilities than for additional hospitals.

"Your committee heartily recommends the approval of the recommendation of the technical committee stressing the use of existing hospital facilities. The stability and efficiency of many existing church and voluntary hospitals could be assured by the payment to them of the costs of the necessary hospitalization of the medically indigent.

"3. Under Recommendation III on Medical Care for the Medically Needy: Your committee advocates recognition of the principle that the complete medical care of the indigent is a responsibility of the community, medical and allied professions, and that such care should be organized by local governmental units and supported by tax funds.

"Since the indigent now constitute a large group in the population, your committee recognizes that the necessity for state aid for medical care may arise in poorer communities and the federal government may need to provide funds when the state is unable to meet these emergencies.

"Reports of the Bureau of the Census, of the U. S. Public Health Service, and of life insurance companies show that great progress has been made in the United States in the reduction of morbidity and mortality among all classes of people. This reflects the good quality of medical care now provided. Your committee wishes to see continued and improved the methods and practices which have brought us to this present high plane.

"Your committee wishes to see established well coördinated programs in the various states in the nation, for improvement of food, housing, and the

other environmental conditions which have the greatest influence on the health of our citizens. Your committee wishes also to see established a definite and far reaching public health program for the education and information of all the people in order that they may take advantage of the present medical service available in this country.

"In the face of the vanishing support of philanthropy, the medical profession as a whole will welcome the appropriations of funds to provide medical care for the medically needy, provided, first, that the public welfare administrative procedures are simplified and coördinated; and, second, that the provision of medical services is arranged by responsible local public officials in coöperation with the local medical profession and its allied groups.

"Your committee feels that in each state a system should be developed to meet the recommendation of the National Health Conference in conformity with its suggestion that 'The rôle of the federal government should be principally that of giving financial and technical aid to the states in their development of sound programs through procedures largely of their own choice.'

"4. Under Recommendation IV on a General Program of Medical Care: Your committee approves the principle of hospital service insurance which is being widely adopted throughout the country. It is susceptible of great expansion along sound lines, and your committee particularly recommends it as a community project. Experience in the operation of hospital service insurance or group hospitalization plans has demonstrated that these plans should confine themselves to provision of hospital facilities and should not include any type of medical care.

"Your committee recognizes that health needs and means to supply such needs vary throughout the United States. Studies indicate that health

needs are not identical in different localities but that they usually depend on local conditions and therefore are primarily local problems. Your committee therefore encourages county or district medical societies, with the approval of the state medical society, of which each is a component part, to develop appropriate means to meet their local requirements.

"In addition to insurance for hospitalization your committee believes it is practicable to develop cash indemnity insurance plans to cover, in whole or in part, the costs of emergency or prolonged illness. Agencies set up to provide such insurance should comply with state statutes and regulations to insure their soundness and financial responsibility and have the approval of the county and state medical societies under which they operate.

"Your committee is not willing to foster any system of compulsory health insurance. Your committee is convinced that it is a complicated, bureaucratic system which has no place in a democratic state. It would undoubtedly set up a far reaching tax system with great increase in the cost of government. That it would lend itself to political control and manipulation there is no doubt.

"Your committee recognizes the soundness of the principles of workmen's compensation laws and recommends the expansion of such legislation to provide for meeting the costs of illness sustained as a result of employment in industry.

"Your committee repeats its conviction that voluntary indemnity insurance may assist many income groups to finance their sickness costs without subsidy. Further development of group hospitalization and establishment of insurance plans on the indemnity principle to cover the cost of illness will assist in solution of these problems.

"5. Under Recommendation V on Insurance Against Loss of Wages Dur-

ing Sickness: In essence, the recommendation deals with compensation of loss of wages during sickness. Your committee unreservedly endorses this principle, as it has distinct influence toward recovery and tends to reduce permanent disability. It is, however, in the interest of good medical care that the attending physician be relieved of the duty of certification of illness and of recovery, which function should be performed by a qualified medical employee of the disbursing agency.

"6. To facilitate the accomplishment of these objectives, your committee recommends that a committee of not more than seven physicians representative of the practising profession, under the chairmanship of Dr. Irvin Abell, President of the American Medical Association, be appointed by the Speaker to confer and consult with the proper federal representatives relative to the proposed National Health Program."

Dr. H. H. Shoulders, Speaker of the House of Delegates, appointed the members of the Committee to Confer and Consult with Proper Federal Representatives as follows:

IRVIN ABELL, M.D., President, A.M.A.,
Chairman

WALTER F. DONALDSON, M.D., Pittsburgh,
Pa.

WALTER E. VEST, M.D., Huntington, W. Va.

FRED W. RANKIN, M.D., Lexington, Ky.,
Section on Surgery

FREDERICK E. SONDERN, M.D., New York,
N. Y.

HENRY A. LUCE, M.D., Detroit, Mich.

E. H. CARY, M.D., Dallas, Tex.

DRS. ROCK SLEYSTER, President-Elect, and
OLIN WEST, Secretary, were declared by the
Speaker to be members of this committee,
ex-officio.

The President of the United States has appointed the Interdepartmental Committee to Coördinate Health and Welfare Activities and the Technical Committee on Medical Care to represent the federal government, and October 31 (1938) has been set as the date for the Conference. The committee of the American Medical Association is imbued with the hope and finds much to encourage it in the belief that a joint consideration of the data and plans accumulated by the Interdepartmental Committee and those available from the study of the American Medical Association will suffice to reconcile the differences heretofore existing as to the procedure to be followed in making a proper and sufficient distribution of health facilities and to see a realization of the objectives to which both groups are committed, namely, the provision of good medical care for all the people; the development of comprehensive preventive and public health services; the development of appropriate measures to combat specific health problems; and a continuous, orderly improvement of the distribution of medical services and hospital facilities, both by geographic and economic divisions.

The Public Health Aspects of Medical Care*

From the Standpoint of Public Health

C.-E. A. WINSLOW, DR.P.H., F.A.P.H.A.

*Professor of Public Health, Yale School of Medicine,
New Haven, Conn.*

MR. ALTMAYER has an obvious right to speak for the Interdepartmental Committee to Coördinate Health and Welfare Activities of the federal government; and Dr. Abell has an obvious right to speak for the medical profession as organized in the American Medical Association. I am in a less fortunate position. When I was asked to address you from the standpoint of the consumer I thought—how can I—how can anyone—represent the consumers of the United States—the farmers of our great Central Basin, the steel workers of Chicago, the textile operatives of Rhode Island, the miners of Pennsylvania, the automobile mechanics of Detroit, the stockbrokers of New York, the bankers of Boston, the ranchmen of Texas, the dock laborers of San Francisco, the cotton pickers of Alabama, the hill-billies of the Appalachians, the storekeepers of Keokuk?

Yet it is very important that the consumer should be represented, however imperfectly. The purpose of medicine is to serve these manifold individual citizens. The physician exists

for the patient, not the patient for the physician. And if any one group of persons is to speak for the consumer in this field, it is surely the public health group. The health officer is, after all, the only individual in a given community who is primarily responsible for the health of all the people in that community. The public health profession does, in fact—always and everywhere and in a unique sense—represent the health interests of the consumer; and this afternoon I have been asked to represent the public health profession.

Our responsibility in this connection has not been unrecognized in the past. Twelve years ago, the President of the American Public Health Association* suggested the following four fundamental principles operating in this field; and they seem to me as valid in 1938 as they were in 1926.

1. Future progress in the reduction of mortality and in the promotion of health and efficiency depends chiefly upon the application of medical science to the early diagnosis and preventive treatment of disease, particularly organic diseases of adult life and mental diseases and maladjustments at all ages.

2. The purely individualistic practice of medicine as it has existed in the past must

* Read at a Special Session on Public Health Aspects of Medical Care of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 26, 1938.

* A.J.P.H., 16, 11:1084 (Nov.), 1926.

be increasingly supplemented by some form or forms of organized medicine which will offer to the individual modern scientific medical care including laboratory and specialized consultation service on an economic basis which will facilitate its application to the prevention of incipient disease—probably on some basis which involves payment of the physician through a common fund for the supervision of the health of an individual rather than for the treatment of a specific ailment.

3. The health officer as an official responsible to the community for the promotion of the public health in all its possible aspects should consider it his primary responsibility to work out in coöperation with the medical profession a wise solution of this problem—a solution which will preserve and maintain all that is best in the noble tradition of the healing art.

4. In the last analysis, it will be the duty of the health officer of the future to see that the people under his charge, in city or country, in palace or tenement, have the opportunity of receiving such services as that outlined above and on terms which make it economically and psychologically easy of attainment; and, himself, to furnish such service if and when it cannot be provided in other ways.

Today, at last, such ideals as those outlined above seem actually within the scope of attainment; and that this is true is primarily the result of the extraordinary National Health Conference held in Washington on July 18–20 last. As Surgeon General Parran said at that time:

Those of us who are concerned with the progress of medical science usually think that the great events of medicine occur only in the research laboratory or the operating room. We are witnessing here in Washington another kind of progress in medicine—an effort to put medical science to work. The National Health Conference may well be the greatest event in medical science in our time.

This Conference was significant for many reasons, but, first and foremost perhaps, because it definitely and finally demonstrated the urgent and critical need for prompt and effective action. To many of us, the report of the Committee on the Costs of Medical Care in 1932 made this need reasonably clear;

but there have been those who doubted, those who attempted to minimize the pressing nature of the problem. As a result of the National Health Survey of nearly 3 million persons in 800,000 families conducted by the U. S. Public Health Service through the coöperation of WPA, those doubts can exist no longer and those efforts to divert attention from the problem must inevitably fail.

“Let’s look at the record.” Fifty million Americans in families receiving less than \$1,000 income a year; one-third of the 35 million children in the United States in families unable to make appreciable payments for private medical care.

Morbidity and mortality increasing steadily and progressively as income decreases; for the 10 most important diseases, a death rate almost twice as high among unskilled laborers as among professional men; workers in industry showing a life expectancy approximately 8 years less than that of non-industrial workers.

Medical care actually received going steadily down in lower economic levels as the need for medical care increases; 1 person out of 4 among the 40 million people in the relief and marginal groups receiving no medical care whatever for disabling illness lasting 1 week or more; nearly a quarter of a million women in 1936 without the care of a physician in childbirth.

Over 40 per cent of the counties in the United States without a registered general hospital to serve their 17 million people.

More than two-thirds of the counties of the United States, and an even larger proportion of its cities, without full-time professional health officers; two-thirds of our rural areas without child health centers or clinics; only 5 states with adequate sanatorium facilities for tuberculosis; programs for control of syphilis and industrial diseases incom-

plete, and those for cancer and pneumonia control and for mental hygiene scarcely even initiated, except in half a dozen states.

The silence at Washington after Paul Kellogg interrupted a somewhat acrimonious debate by asking the simple question, "Does anyone seriously challenge the statements of need that were made in the papers this morning and were amplified this afternoon?" was one of the most dramatic moments of the conference.

The second outstanding feature of the Washington Conference was the program of action to meet these needs, presented with extraordinary skill by the Technical Committee on Medical Care of the Interdepartmental Committee—a program which formed the major basis for the last 2 days of discussion. This report was notable for the care with which it had been prepared, for its soundness and, particularly, for its balance. It was not a program for public health expansion, a program for the extension of medical service, a program for health insurance. It was a complete, coördinated, interlocking, dovetailing health program for the nation, in which all these objectives have their just and proper part.

The *first* recommendation of the Technical Committee—and one of the two for which it suggested special priority—was a major extension and modernization of our basic health services. This program, to be accomplished by the methods of federal grants-in-aid so successfully applied already on a small scale under the Social Security Act, has been fully discussed by Mr. Altmeyer. It needs no argument before my present audience and appears to be unanimously supported.

The *second* recommendation — also given special priority by the committee — deals with the provision of adequate hospital facilities for all the people of the United States and the meeting for

the first 3 years of one-half the maintenance charges for necessary construction. This need was challenged by a few speakers at the National Health Conference on the basis of a survey which followed the extremely naïve plan of drawing a circle of 30 mile radius round every hospital of any size and considering each county as well served which at any point was cut by such a circle. On this basis, a single 10 bed hospital would be adequate for the city of New York. A study of the data presented by the Technical Committee at Washington will convince any competent student of the soundness of its conclusions.

The *third* recommendation dealt with the medical care of the 20 million persons now receiving public assistance in one form or another and of the additional 20 millions, so close to the emergency level that they can purchase medical care only at the expense of food, shelter, and other basic essentials of life. Current provision for these groups — though furnished to a considerable extent by many state and local governments, supplemented by the generosity of voluntary organizations and professional practitioners — meets only two-thirds of their vital needs. A maximum expenditure of \$400,000,000 is proposed for this purpose, approximately one-half to come from federal funds, as in the case of expenditures under recommendation 1 and 2. This proposal will certainly not be opposed by the professions concerned or by the ultimate consumer. The question how such services are to be administered is, however, of considerable importance. I myself feel it essential for maximum effectiveness that all tax supported medical services should be provided by the one government bureau which is primarily equipped to furnish medical direction, the health department; and it was a source of great gratification to me that the speakers representing the welfare agencies at

the Washington Conference unqualifiedly accepted this view. It seems to me of major importance that the health officers, federal, state, and local, should be ready to accept the opportunity which is now offered to assume primary responsibility for extra-mural tax supported medical care. If this opportunity should be lost, it may not be presented again.

The *fourth* recommendation of the Technical Committee dealt with the more difficult and more controversial problem of medical care for persons on a higher income level than those who should receive free medical care under recommendation 2. At the bottom of the economic scale is "a third of the nation" who can pay none, or but a small part, of the cost of medical care. At the top is a small group who can meet even the emergency costs of unexpected illness. The great bulk of our population lies between. They can pay the average cost of medical care, some \$30-\$36 per person per year. But they cannot, as individual families, budget for the random catastrophe of serious medical emergencies. There is but one hope for this group (and for the professional personnel serving this group), the spreading of the costs of medical care over a number of families and over a period of time. It is a method which is simple, logical, inevitable. It is a method which, in some form or another, has been adopted by almost every civilized country in the world. The actual spreading of the economic burden of medical care can be accomplished, as the committee points out, either by taxation, by insurance, or by a combination of the two. "Experience in many countries suggests health insurance for urban and industrial areas and public medical services for rural and agricultural areas." The committee recommends federal grants-in-aid to the states for the development of broad programs of medical care along one or both of these

lines. It is obviously essential that professional standards of service should be safeguarded in any program of this kind, and the formulation of such safeguards is the business of the medical profession. The method by which the consumer elects to pool his financial resources to pay for medical service is, as I see it, *his* business which he must accomplish according to his own desires and with the counsel of the appropriate experts in this field, the statistician and the economist.

Finally, the *fifth* recommendation, with which we are here less directly concerned, recommends the development of a national program for insurance against the financial losses due to disability.

The first striking feature about this epoch making report was its presentation to the Conference by a committee of 5 independent government departments working in coöperation. You and I can remember occasions on which different federal agencies working in the health field were not always in complete agreement. Yet here were representatives of nearly half the President's Cabinet presenting a unanimous program for national health. For this miracle of coördinative action we owe a deep debt to one of the ablest and finest and most useful women in these United States, Josephine Roche.

The second striking feature of the Conference was the astounding consensus of support for its main objectives from the groups represented. I have, for 10 years, sat in at discussions of this subject, in Washington and elsewhere, but never before has it been discussed face to face with those great agencies which really represent the American people. When this health program received, as it did receive, in general principle and in broad method, the support of both the great labor organizations of the country, of the agriculture of the country, of the busi-

ness of the country, with that splendid phrase of Mr. Taussig's, "That a tax supported health program was not a burden on industry but a subsidy to industry," and with that other magnificent phrase of his, that "democracy should be a sword as well as a shield"; when we heard the support of the women of the country, and the parents of the country, and the youth of the country, and the radio and the press—this was an event of the most profound significance. The A.F. of L. and the C.I.O., the American Farm Bureau Federation, the Amalgamated Clothing Workers, the United Automobile Workers, the United Mine Workers, the Y.W.C.A., the Federation of Women's Clubs, the National Congress of Parents and Teachers—all were represented and all in favor. As Hall and Kellogg said in their admirable review in *The Survey*:

Alongside physicians, surgeons, dentists, nurses, hospital managers, and public health men, ranged representatives of labor, industrial and farm organizations; of women's clubs, bodies of consumers, parent-teacher associations, youth organizations, coöperatives; social workers, educators, public welfare administrators and their kin. Here were the patients, if you will: consumers, and spokesmen for would-be-consumers. They had come to say in no uncertain terms that they and their fellows believed in medical care and wanted more of it for everybody. They drove home that, because of locality or income, such care was simply unavailable or inadequate for great numbers of the people they represented; and that those numbers ran into millions. In equally outspoken terms, they believed such care could and should be brought within reach of those millions.

To me, it seemed that I had all my life been hearing about democracy; but that now at last I had seen its face.

The program thus presented and thus endorsed was no cut and dried formula. It was broad, general, flexible—with every opportunity for local initiative in planning and with all but a fraction of the funds for overhead and research to be spent, as in the present Social Se-

curity Act, by state and local governmental authorities.

In the working out of such a program, there are many difficult problems to be solved. One of the most thorny of these is the problem of health insurance, where we find the American Medical Association on one side and all of the most politically powerful consumer groups of the nation on the other. In my judgment, this problem does not relate to the national health program as such, since under recommendation 4 the choice between tax supported service and insurance is left to the states. The conflict will come in the individual states; and in this conflict I seriously question whether the American Medical Association has chosen its position wisely. If provision is to be made for distributing the cost of medical care for the great bulk of our population in the middle economic level—and that it must and will be made seems certain—it can be done in a given area only by tax support or by insurance funds. In making the choice it seems to me that a tax supported organization is essential for preventive service and for the care of the indigent; but that, for families on a higher economic level, in urban areas, insurance has distinct advantages; it promotes the self-respect and sense of responsibility of the patient while it leaves the medical profession as a whole in an independent and more authoritative position. Under a system of health insurance in England, for example, the British Medical Association is taking a position of unqualified leadership.

In all that may be done, I would particularly urge that emphasis be laid upon quality as well as quantity of service. I am personally as much concerned about the people who receive bad medical care as about those who receive no medical care.

We have no right to collect either tax money or insurance funds without being reasonably sure that real value is re-

ceived. As Dr. Hugh Cabot rightly said in Washington:

The minute the government begins to suggest the method and to provide the funds, it assumes responsibility for the product, at once; it must assume a responsibility for the maintenance and improvement of standards, not only in medical care but in medical education and in research. . . . There are very large areas in this country where the practice of medicine as at present carried on is medieval. The physicians practising there are members, properly so, of their county societies and therefore necessarily of the American Medical Association, but who says whether or not the article which they are selling is a first-class article or . . . one which is expensive at any price?

Neither legislation nor long-distance supervision can, in the long run, guarantee a good quality of medical care. There is only one agency which can insure that physicians operate at maximum efficiency and that is the medical profession itself. But for this purpose the medical profession must be organized—and organized in service groups. The county medical society, like the government, can discipline the most extreme deviations from professional practice. It cannot do more. The organization of groups of physicians for actual service, as in a well organized hospital staff, furnishes the only machinery by which standards can be kept at the highest possible point, through day by day contact and day by day inspiration of the best leadership available. That is why I consider the principle of group practice to be as important as that of group purchase; though this, again, is a personal opinion which relates not to the National Health Program but to details in its working out. It is clear, however, that the medical profession is not now organized effectively for quantity, because physicians are in large measure not where they are needed and it is not now organized in such a way as to give the maximum possible guarantees of quality. This is a question which must be solved, in so

far as may be possible, by the medical profession, through their medical societies, and perhaps better through their hospital staffs, and by the leadership of the health officers of the community.

Throughout the working out of the whole National Health Program are social and economic problems which primarily concern the consumer and his needs and professional problems which primarily concern the physician and his science. They must be solved by patient and open-minded and unselfish deliberation and consultation. It is a cause for deep satisfaction that the American Medical Association at its September meeting has provided for a program of coöperation and has established machinery for making that coöperation effective. We owe, too, a deep debt to the independent Committee of Physicians which has done so much during the past 2 years to crystallize thinking on this matter and to bridge the gap between the producer and the consumer of medical service.

The leaders in this national program will need counsel and guidance; and, above all, they will need the wisdom that can come only from actual experimentation. That is why I feel that the experiments made in industrial medicine, in university medicine, in hospital insurance, are of incalculable value. Above all, the pioneering experiments in coöperative medicine and group health insurance including medical care, are of extreme significance. Nothing seems to me more regrettable than opposition to such experiments—experiments conducted on a voluntary basis and under competent medical guidance. Whether such opposition is in violation of the anti-trust laws, as the U. S. Attorney-General believes, I do not know. But I am certain that it is shortsighted to attempt to block the one avenue of approach which maintains to the fullest degree the independence of the patient and the leadership of the physician. I

am convinced that the principle of freedom of choice of physician should be furthered to the maximum degree; but I should like to emphasize that any acceptable definition of freedom of choice of physicians must include the right of a group of patients to choose a group of physicians for their service. I am certain that any attempts to interfere with that freedom cannot, in the long run, be maintained.

One word more. At the July meetings it was made abundantly clear that criticism of the existing situation is not criticism of the medical profession any more than opposition to the acts of the present federal administration involves an assault on the American home or on the memory of George Washington.

Nothing impressed me more deeply at this Conference than the admiration and affection with which such leaders as Hugh Cabot and Adolph Meyer and Alice Hamilton and Borden S. Veeder and Robert deNormandie and Allan M. Butler and Robert Osgood and John Peters were received by an audience which was strong in its opposition to certain policies of "organized medicine." This was not an attack on the doctor. It was rather a most touching appeal to the medical profession. It has been the boast of the medical profession, and the just boast, and the source of proper pride, that if a woman came with a sick child to an individual physician and said, "My child is suffering and we want you to care for it," he never failed to respond. Now what happened in that week in July was that the representatives of millions of men and women in the United States came to the medical profession as a group and said, "Our people are sick and suffering and we want medical care for them, and we want means provided by which we can pay." Is it possible, is it conceivable that that appeal is going to be rejected? I think not.

The newer challenges of public health

which more and more involve problems of direct clinical service force us as health workers to confront the basic issues involved in the Washington Conference. If these issues are to be carried to a successful conclusion, our health officers must lead in the advance. In large degree you are already showing such leadership. It is to me a source of increasing pride to note how the major advances in modern medical service—in the control of cancer, of syphilis, of pneumonia—are actually being made by the practising physician, but under the stimulus and guidance of the state and local health officers. You are today leading in these fields. You must carry on with the same initiative all along the line.

A year ago Miss Josephine Roche presented a direct challenge to our organization. She said:

A far step forward would be taken, I think, if the American Public Health Association formally recognized the problem of the present unequal distribution of medical services, and the widespread human needs of today, and charged a special committee to cooperate with the U. S. Public Health Service in extending through proper methods the long accepted functions of public health work to meet modern demands and needs of our people. I hope this action may be taken.

The National Health Conference has made this challenge an imminent one. I earnestly hope that our Association may provide really effective machinery for cooperating with the President's Interdepartmental Committee which is charged with the development of the splendid plans outlined in July.

To many of us, it seems that at last our dreams of 20 years are coming true. Yet the actual realization of the vision cannot come at Washington, but in the local communities throughout the nation. The answer lies in *your* hands. In this year of grace, you stand in the mountain pass and look down into a new land—a land of challenge but a land of incalculable opportunity.

DISCUSSION

FRED K. HOEHLER

Executive Secretary, American Public Welfare Association, Chicago, Ill.

IT is a privilege to participate in this session of the American Public Health Association Conference because I believe you are making history. I can very well agree with most of the principles presented in the papers of this afternoon, particularly in the emphasis given to the need for a high quality of service in any program of medical care which may be adopted by the national or state governments. If you will permit I would like to direct my remarks to the phases of public administration involved in the program discussed here this afternoon. I shall do this in the light of two very sound principles of public administration. First, the administration of related public services should be in a single department under competent direction. Second, responsibility for spending public money should be placed upon public officials who can be held accountable. Dr. Abell's concern for sound administration and quality of service is shared by the American Public Welfare Association and all those who are today serving the states in this field.

Mr. Altmeyer has suggested that there is considerable confusion and some question as to whether the administration of medical care services belong with the welfare or health department. In our present experience most of the medical care provided by public service is under the direction of welfare departments. This is so because our conception of public medical care has been limited to those who are dependent. Then, too, welfare departments had the money for this service and it is natural that the responsibility should have been placed with welfare departments. Another factor in this

present situation is the actual resistance on the part of many health departments in assuming responsibility for medical care, and in some places pressure from local and state medical societies against any effort to place medical care responsibility with health departments.

Economy of operation and administration depends on supervision of accounting and standards just as well as it does on competent direction. We have some concern in this country in the farming out process of public services, and it emphatically has not worked except where there was administrative control and supervision from the sources of funds. It is necessary, therefore, that such public funds as may be spent for medical care be spent under the immediate direction and supervision of public agencies. It is not necessary to duplicate facilities just to spend public funds if those agencies, either public or private, are adequate to meet the needs of the community. It is entirely possible, through payment for services rendered for one public department, to buy services from another or even from a private agency competent and willing to render such services. There must be close coöperation and relationships between welfare and health services regardless of where the responsibility for administration of medical care will eventually reside. This type of coöperation exists today in several states. New York, where the program is at present handled by the welfare department, is an example of the splendid coöperation between the welfare and the health services.

All of us decry, with Dr. Abell, political manipulation in social services, and those who are in attendance at this

meeting and those of us who have responsibility in advising with and directing the broad public welfare services must strive relentlessly to remove political manipulation, whether it is professional or partisan, from the administration of those services. Most of us who are familiar with present arrangements in the subsidy system for instance will agree there is as much politics in the subsidy programs as in both of our national political parties. During the past 10 years of experience of administering coöperative programs between state and local, and state and federal governments, we have learned the necessity of protecting standards of personnel as well as quality of service from all kinds of political manipulation, and the future looks rather brighter as we find the American public expressing a real concern for protection of these standards.

I would like to say just a word about where this service should reside. After watching the operation for the past few

years, it is my considered opinion that the service of medical care, which should realistically go beyond dependent groups in our communities, belongs under professional direction and if at all possible with the health department, but I can assure you that no honest public administrator will assign this job to a department with half-hearted interest or an indifferent attitude even though it be a public health department. In some states it might be better that it reside where it is until health departments and health officials have a more whole-hearted acceptance of the program of medical care.

And, finally, as we move into these new fields, may we avoid the confusion which so often attends the introduction of new governmental services. Since the National Health Conference in July the way seems clear, the call of the people has been a clarion cry, and may all the welfare services join to answer that call.

Questionable Value of Skin Testing as a Means of Establishing an Epidemiological Index of Tuberculous Infection *

L. L. LUMSDEN, M.D., W. P. DEARING, M.D., AND
R. A. BROWN, M.D.

*Medical Director; Passed Assistant Surgeon; and Consultant in
Tuberculosis Studies; U. S. Public Health Service,
New Orleans, La.*

STATISTICAL studies¹ in recent years have shown a striking regional distribution of tuberculosis mortality in the United States. The distribution is especially interesting in the section comprising the central and southeastern states. With a view to determining the factors importantly operative in contrasting situations, the U. S. Public Health Service with the coöperation of the State Health Departments of Alabama and Tennessee, the local health departments directly concerned, and the Tennessee Valley Authority, began in 1936 an intensive detailed study of tuberculosis causation in Coffee County in southeastern Alabama and in Giles County in south central Tennessee. These two counties were selected because they, respectively, are fairly representative of the low tuberculosis rate coastal plain region and of the high tuberculosis rate Tennessee Valley region. Both are very largely rural agri-

cultural counties. The distributions of their populations by land area, by town, village, and open country districts, and by race and nationality are much the same. Giles County appears considerably more prosperous than Coffee County. The mortality statistics, however, show that for the 9 year period 1929-1937 the average annual death rate from tuberculosis per 100,000 population was 116.4 among whites and 210.2 among negroes in Giles County, as against 12.5 among whites and 59.4 among negroes in Coffee County. The recorded rates for the last 9 years are shown in Table I.

The study has included a complete house-to-house survey and family canvass of the two counties for the collection of every datum ascertainable by such procedure which appeared likely to throw any light on the problem. Among the findings from the family canvass is that the difference between the two counties in actual tuberculosis mortality and morbidity rates has been during the last 9 years somewhat greater than is indicated by the state and county official records. The fact

having been established that the incidence rate of demonstrably damaging or of fatal tuberculosis is at least 9 times higher among whites and about 4 times higher among negroes in Giles County than in Coffee County, the question arose whether the difference is due to a difference in extent and degree and kind of distribution of the specific infectious agent or to a difference in operation of environmental and other factors affecting the human host. As it appeared probable that the proportion of persons exposed through familial and other direct personal contact to open cases of the disease during recent years was much larger in Giles County than in Coffee County, a further question which arose was whether the incidence of subclinical tuberculous infection, especially among young persons, was much higher in the former than in the latter county. We, therefore, undertook to carry out along authenticated lines a program for the purpose of

establishing for each of the counties an epidemiological index of tuberculous infection.

PROGRAM

The program comprised tuberculin skin tests by the Mantoux method and X-ray examinations of the chests of representative age-sex-race-community groups totalling about 12,000 persons, or about 20 per cent of the population of each county. In consultation with the authorities of the Henry Phipps Institute and the National Institute of Health it was decided to use in the skin tests one of the preparations of purified protein derivative of tuberculin ("Tuberculin, P.P.D.") because of the reported superiority in potency, specificity, stability, and uniformity of such preparations.² We obtained from a pharmaceutical company, hereinafter designated Co. "A," a supply of P.P.D. in tablet form. Co. "A" is one of the two companies manufacturing and dis-

tributing P.P.D. preparations in the United States under authentically approved conditions.³ Following the lead of the workers⁴ in the Williamson County (Tenn.) project we have X-rayed the chests of all persons tested with the tuberculin preparation whether positive or negative to that test. In our routine skin tests we have used 0.0005 mg., or one-tenth of the usual second strength dose, of the P.P.D. preparation. We were advised⁵ that such dosage would give positives for about 93 per cent of those who would give positives with the usual full second strength dose. Our methods of testing, X-raying, and reading were in conformity with established standards in every respect. School children were the first to be studied. This paper deals mainly with our findings in 4,400 school children in the two counties.

FINDINGS

Of 177 white children ranging in age from 6 to 19 years at the first school tested in Giles County only 14.7 per cent showed positive reactions. This percentage was surprisingly low in view of the reported findings of 43.4⁶ and 61.9⁷ per cent positives to two-dose tests with old tuberculin among white school children in Williamson County, Tenn., and Lee County, Ala., respectively, each of which counties has a recorded death rate from tuberculosis much lower than that of

Giles County.⁸ Suspecting there might be something wrong with our supply of P.P.D., we sent a sample of it to the National Institute of Health. The report returned was that the sample of our supply gave on sensitive guinea pigs corresponding reactions to those of the P.P.D. used there for such testing. Throughout our first round of routine testing among school children in Giles County and Coffee County we continued to use this supply of Co. "A" P.P.D. in the same dosage so that the results in the two counties would be comparable. However, for our information, we carried out among a number of children in each county (1) tests with full second strength dose of P.P.D. of Co. "A" and other tuberculin preparations, and (2) duplicate tests (at the same time in opposite forearms of the same individuals) with this preparation and one of the following preparations: (a) lot 511 of old tuberculin made by a pharmaceutical company (Co. "B") and used in Williamson County and generally by the Tennessee State Health Department; (b) lot 771 of old tuberculin made by Co. "B" and used in Lee County and generally by the Alabama State Health Department; (c) a lot of old tuberculin made by and used extensively by the Michigan State Health Department; and (d) a P.P.D. preparation obtained from Co. "C," the other of the two pharmaceutical companies whose outputs of P.P.D. are

reported to be checked authoritatively by clinical trial of every lot manufactured.⁹

The results of our first round of tests are shown in detail in Tables II, III, and IV.

A total of 701 children in several

different schools in the counties who were negative to 1/10 second strength dose of Co. "A" P.P.D. were retested with full second strength dosage (0.005 mg. of P.P.D. or 1.0 mg. of O.T.). Of 333 retested with Co. "A" P.P.D. 11.7 per cent were positive, of 164 retested

TABLE IV

Results of Duplicate Testing in Opposite Arms of the Same Individuals with Co. "A" P.P.D. and Other Tuberculin Preparations among School Children in Coffee County, Ala.

Preparation, Dosage and Site of Injection	Number Tested	Per cent Positive to Both Preparations	Per cent Positive to Co. "A" P.P.D. Only	Per cent Positive to Other Preparation Only
In Left Arm: Co. "A" P.P.D. 0.0005 mg.				
In Right Arm:				
(1) Co. "C" P.P.D. 0.0005 mg.	105	5.7	0.0	25.7
(2) Michigan State Health Department O.T. 0.1 mg.	62	8.1	3.2	11.3
(3) Co. "B", Lot 511, O.T. 0.1 mg.	171	17.5	1.2	35.1
(4) Co. "B", Lot 771, O.T. 0.1 mg.	112	7.1	0.0	71.4
In Left Arm: Co. "A" P.P.D. 0.005 mg.				
In Right Arm:				
Co. "B", Lot 771, O.T. 1.0 mg.	173 *	15.0	0.0	73.4

* This group had been found negative to previous test with 0.0005 mg. of Co. "A" P.P.D.

with O.T. of lot 511 of Co. "B" 31.1 per cent were positive, and of 204 retested with O.T. of lot 771 of Co. "B" 80.9 per cent were positive (see Table III).

Among 450 children in several different schools in Coffee County given simultaneous duplicate tests with 1/10 second strength dose of Co. "A" P.P.D. and with similar dosage of another preparation the results were as follows: positive to P.P.D. of Co. "A" 11.8 per cent, to lot 511 of O.T. of Co. "B" 52.6 per cent, to lot 771 of O.T. of Co. "B" 78.6 per cent, to Michigan State Health Department O.T. 19.4 per cent, and to P.P.D. of Co. "C" 31.4 per cent (see Table IV).*

Since the first round of testing with P.P.D. of Co. "A" in the two counties 460 previously untested children attending three schools in Giles County have been given, under extreme precautions to eliminate possible technical error, simultaneous duplicate tests with P.P.D. of Co. "C" and O.T. of lot 863

of Co. "B." The findings are shown in Table V. To 1/10 of second strength dosage 12.6 per cent were positive to the P.P.D., and 32.6 per cent to the O.T. Of those who were negative to the middle dosage of both preparations 280 were retested, 2 days after the first test, with full second strength dosage of each preparation. Of these children so retested, 9.7 per cent were positive to the P.P.D., and 40.7 per cent to the O.T. Of 93 children negative to the P.P.D. and positive to the O.T. in middle dosage only 19 were positive to the P.P.D. when the dose of that preparation was increased tenfold.

These strikingly variable results indicate that different preparations of tuberculin now used extensively by our health agencies vary greatly in potency and/or specificity and signify that the percentage of positive reactors to skin tests among school children, and inferentially among other general population groups, depends largely upon the particular preparation of tuberculin

* In the body of this paper reactions to skin tests with tuberculin preparations are presented as positive or negative in accordance with the standards of the National Tuberculosis Association. Reactions with areas of induration of 5 millimeters or more in diameter are recorded as positive. Reactions with erythema but without induration, those with areas of induration of less than 5 mm. in diameter whether or not accompanied by erythema and those without either induration or erythema being apparent are recorded as negative. The readings of the degrees of reaction also were in accordance with those standards—areas of induration of 5 to 10 mm. in diameter being read as 1+, those of 10 to 20 mm. as 2+, those exceeding 20 mm. as 3+, and those with both induration and definite necrosis as 4+. Readings were made from 48 to 72 hours after the injections. In our series of duplicate tests with different tuberculin preparations in similar dosages interesting discrepancies were observed not only in percentages of positives but also in degrees of reactions among the positives in opposite arms of the same individuals. The following is an example:

Seventy-one white children in a grammar school in Elba, Coffee County, Ala., were given duplicate tests with 1/10 of second strength dosage (0.0005 mg.) of Co. "A" P.P.D. and Co. "C" P.P.D. Careful measurements in millimeters were made of the areas of induration in the 22 positive reactions. The results were as follows:

	Positive to Both		Positive to Co. "C" P.P.D. Only		Positive to Co. "A" P.P.D. Only
	Co. "C" P.P.D.	Co. "A" P.P.D.			None

* Single Preparation Test

used in making the tests. Satisfactory epidemiological measurements cannot be made with such varying "yard-sticks."

Our findings appear to cast grave doubt not only on the validity of recorded and exploited rates of subclinical tuberculous infection which have been established in different communities for the same period or in one community for different periods of time solely on a basis of results of skin testing with different preparations of tuberculin but also on the significance of findings in two or more communities tested at the same time by the same method with the same dosage and the same identical preparation of tuberculin.

Our first round of routine tuberculin testing comprised 2,126 school children in Giles County and 1,828 in Coffee

County. Those tested are regarded as fairly representative in every way of the total school child populations of the two counties. The tests in both counties were made by the same field force under the same executive direction and supervision with the same preparation of tuberculin (P.P.D. of Co. "A") in the same dosage. A striking finding was that, notwithstanding the very marked difference between the two counties in tuberculosis mortality rates, the tests gave very nearly the same percentage of positives in each of the counties (see Table II). In Giles County 13.8 per cent of the 1,657 white school children and 22.4 per cent of the 469 colored school children tested were positive, and in Coffee County 14.9 per cent of the 1,355 white school children and 19.5 per cent of the 473 colored school children tested were positive. Retests with

full dosage of both Co. "A" P.P.D. and Co. "B" O.T. of lot 771 showed a considerably higher percentage of positive reactors to each preparation in Coffee County than in Giles County (see Table III).†

Another striking finding was the very marked difference between the two counties in the percentage of school children showing definite X-ray evi-

dence of calcified pulmonary areas of a sort regarded by the authorities generally as unquestionably healed or arrested primary lesions of tuberculosis. In Giles County 43.2 per cent of the white school children and 25.8 per cent of the colored school children, and in Coffee County only 0.6 per cent of the white school children and only 1.1 per cent of the colored school children ex-

† In the course of these studies it was observed, however, that the incidence of 2 to 4+ positive reactions was much higher in Giles County than in Coffee County.

The following table shows the degrees of reaction recorded among 1,657 white children in Giles County and among 1,355 white children in Coffee County resulting from tests with 0.0005 mg. of Co. "A" P.P.D.:

Reaction	Giles County		Coffee County	
	No.	Per cent	No.	Per cent

* X-ray positive signifies Calcified Primary Areas except for 2 pneumonic childhood type infiltrations, one of which was positive to both preparations and one negative to both.

amined showed such lesions (see Table VI). Thus the incidence of pulmonary calcified areas among school children was over 40 times as high in Giles County as in Coffee County. An interesting feature in this connection is that among the school children in Giles County calcified areas were nearly as frequent among those negative as among those positive to our routine skin testing with P.P.D. of Co. "A." Of the white children positive to P.P.D. 46.5 per cent and of those negative to P.P.D. 42.7 per cent showed calcification. Of the colored children 33.3 per cent of the P.P.D. positive and 23.6 per cent of the P.P.D. negative showed calcification. Of the 2,126 Giles County school children examined, 12 showed pulmonary lesions regarded as clinically significant tuberculosis. Of these 12, there were 7 negative and 5 positive to our routine test with Co. "A" P.P.D. Of 2 children found with clinically significant pulmonary lesions among the 1,828 Coffee County school children examined, one was positive and the other negative to the test with P.P.D. of Co. "A."

Table VII shows a somewhat similar lack of correlation between pulmonary calcification and skin sensitivity to two other tuberculin preparations.

Thus the results of tuberculin testing and those of X-raying of chests were far apart as epidemiological indicators.

DISCUSSION

Our herein reported experience with tuberculin testing in practical epidemiological field studies of the causation of tuberculosis is confusing and disconcerting. It causes us seriously to question the validity of the highly authenticated¹⁰ statement that "the incidence of positive reactors to tuberculin among the children and young adults is the best criterion of the tuberculosis problem in any community." Whether the varying results we obtained from the use of different tuberculin preparations were due to differences in potency or specificity of the preparations or to a peculiar allergy among some of the groups of persons tested to something other than tuberculo-protein in some of the preparations are pregnant questions. We do not know the answers. Neither do we know the significance of the lack of correlation between calcification of lung areas and allergy to tuberculin preparations as found by us in Giles County and by Gass, Gauld, Harrison, Stewart and Williams in Williamson County, Tenn.¹¹

We do not know the significance of the remarkable similarity of percentages of positive reactors to the same dosage of the same preparation of tuberculin administered to young persons in Giles County and in Coffee County notwithstanding the very marked difference

between these two counties in mortality and morbidity rates from tuberculosis. We do not know that any of the preparations of tuberculin we used would not have demonstrated sensitivity in the majority of persons with active progressive tuberculosis in the areas of our studies. We do not know the significance of some of the findings recently reported by other workers with respect to (a) the lack of allergy to tuberculin demonstrated at times among some persons with active tuberculosis,¹² (b) the lack of qualitative specificity of intracutaneous reactions to the purified protein derivatives of the various acid-fast bacteria,¹³ and (c) the difference in sensitivity to tuberculin preparations of different skin areas of some identical persons at the same time.¹⁴

Thus, it appears to behoove us and all others engaged or interested in this field of tuberculosis epidemiology to be humble in our ignorance and diligent in our search for new knowledge.

CONCLUSIONS

1. Skin testing with any of the tuberculin preparations now on the market or otherwise amply available as a sole means of establishing an epidemiological index or rate of incidence of tuberculous infection in the general population of a community or region is of questionable value or definitely futile.

2. Further work, both laboratory and field, by properly equipped agencies, for the determination of reliable standards of potency, specificity, uniformity and stability of tuberculin preparations and for the establishment of reliable standard methods of administration and interpretation of tuberculin tests among persons is highly in order.

DISCUSSION

W. T. HARRISON, M.D.

*Surgeon, U. S. Public Health Service, National Institute of Health,
Washington, D. C.*

THE paper by Dr. Lumsden and his coworkers presents certain problems in connection with tuberculin testing which have not been raised heretofore. The Mantoux test as applied to human

beings must, of necessity, as compared with tests on animals, require a first dose which will in the most sensitive individuals produce a minimum number of severe reactions. Consequently, the

first intradermal dose of all preparations is low. As a matter of fact, there is no general agreement among workers in this field as to the proper size of either the first or second test dose of tuberculin for the Mantoux test.

The two lots of Old Tuberculin used in this study have been very carefully tested at the National Institute of Health, both in animals and in adult human beings, in institutions in the Washington area. Both lots are very strong, much stronger than P.P.D. or the International Standard. However, when the dilutions are adjusted to produce comparable reactions in the skin of tuberculous guinea pigs, comparable reactions are also obtained in the skin of the adults tested. It is not known if such results could be obtained in the area in which Dr. Lumsden has worked, and such information can only be obtained by trial.

When 1.0 mg. of one of these lots of Old Tuberculin was injected in 173 school children in Coffee County, all negative to a comparatively large dose of P.P.D., 88 per cent reacted, while only 15 per cent reacted to 10 times the first dose of P.P.D. to which they were all negative. Again, in another group of school children, 88.6 per cent were tuberculin positive to the doses used, which we must admit is extraordinarily high. Thus the whole question of the proper size doses for diagnostic tuberculin is reopened. It may

very well be that the degree of sensitivity elicited by a very large dose is not clinically significant and that the dose should be adjusted to miss these very slightly sensitive individuals. Such questions may only be answered by much field and clinical experience and by using tuberculins of approximately equal strength.

The possible importance of the non-specific factor in connection with the high percentage of reactions following the larger doses of Koch's Old Tuberculin must also be considered. When 1.0 mg. is injected intradermally, we must remember that this represents at least 0.01 c.c. of unconcentrated broth. Those of us who have tried to read uncontrolled Schick tests in older children and adults will recall that at times great difficulty is experienced even after 7 days. It would be much more difficult to read these reactions at 48 hours.

The question of tuberculin standardization has been before the Institute for a number of years. The fact that products in the market vary widely in potency has been well known. A national, and new international, standard is now under consideration. Such a standard will equalize the potency of the world's supply of tuberculin but will not determine what the proper test dose should be. Such information may only be secured as a result of much experience with products of uniform strength.

Preparation and Analysis of Diagnostic Antipneumococcus Serum*

HENRY WELCH, PH.D., EARLE K. BORMAN, M.S., AND
FRIEND LEE MICKLE, Sc.D., F.A.P.H.A.

*Research Microbiologist; Assistant Director; and Director; Bureau
of Laboratories, State Department of Health, Hartford, Conn.*

THE preparation of Neufeld antisera has ordinarily followed the method described by Cooper and Walter¹ with respect to dosage and rest periods. Briefly, that method consists of the intravenous injection into rabbits of washed, formalinized suspensions of pneumococci, sedimented from broth cultures, on 3 successive days followed by a rest period of 4 days, repeating the process for 3 successive weeks. Freshly prepared antigen in graded doses is used for each injection. Rabbits may be bled at the end of the rest period following the third series of injections. Studies at the Massachusetts Antitoxin and Vaccine Laboratory² have shown that a stable heat-killed antigen superior to formalinized cultures can be prepared and used with success over a period of several months.

Sera are usually tested for potency by agglutination tests followed by observance of a satisfactory "Quellung" with homologous-type organisms. Cross-reactions are ordinarily detected by observing Neufeld mounts prepared with heterologous types. Although commercial sera we have purchased have been

found generally satisfactory for sputum typing, much time has been lost in typing specimens rich in specific substance, particularly peritoneal washings from inoculated mice, when dilution of the specimens on a trial and error basis has eventually led to the determination of the type. Had our workers had some way of knowing the potencies of the antisera used, expressed in terms readily translatable into routine practice, valuable time and effort would have been saved.

The purposes of this paper are to describe a short method of preparing these diagnostic antisera and to present certain suggestions regarding standardization of Neufeld antisera based upon analytical serologic studies. Our studies have led us to believe that certain pitfalls of the Neufeld reaction, commented upon by Walter,³ will not be overcome until there is advanced a standard technic for determination of serum potency which will make it possible to express the strength of each serum in terms usable by the diagnostic laboratory.

PREPARATION OF SERA

In a previous publication⁴ a short method was described for the production of streptococcic antisera for the

* Read before the Laboratory Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 28, 1938.

precipitin reaction. The method has been used successfully in these laboratories for the preparation of many types of agglutinating antisera for diagnostic purposes. When this method was applied to the production of Neufeld antisera for the 30 pneumococcus types, it yielded effective sera with weaker cross-reactions than are obtained through longer methods. By the use of boiled antigens the results obtained were better than those afforded by formalized antigens. In a series of 76 rabbits injected by this method only one failed to produce a satisfactory Neufeld serum. This rabbit, immunized with a formalized antigen several weeks old, yielded a serum of high species-specific agglutinin titer. A description of the method follows:

Broth—Infuse 1 part ground, fat-free beef heart with 2 parts of water over night in the refrigerator. Heat to boiling and press through cheesecloth. Add 2 per cent neopeptone (Difco), 0.5 per cent NaCl and 0.1 per cent dextrose. Bring slowly to a boil, filter through cheesecloth and cotton and adjust to pH 8.1. Bring to a boil and filter through medium grade filter paper. Autoclave at 250° F. for 20 min. For freshly isolated cultures it is advisable to add 1 per cent sterile inactivated human serum after sterilization.

Antigen—Centrifugalize 18 hr. broth cultures of type-specific pneumococci, which have recently been passed through mice, until the supernatant broth is clear. Suspend the sedimented organisms in a small amount of physiological salt solution so that the concentration of pneumococci roughly approximates 20–25 billion organisms per ml. This concentration is routinely effected by measurements of density with the Gates' apparatus.⁵ Pipette the suspension into 1 in. diameter test tubes and place in boiling water for 15 min. The suspension after heating is ready for use as stock antigen. For injection, dilute the stock antigen 1:10.

Injection of rabbits—Inject rabbits in the marginal ear vein following the schedule given below:

Day	Dose
1, 2, and 3	0.5 ml.
4, 5, and 6	1.0 ml.
7, 8, and 9	1.5 ml.

On the 10th day bleed the animals from the ear for a potency test. Rabbits ordinarily show a sufficiently high titer to be bled on the 11th day. It has been our practice to take only 50 ml. at that time followed by injection of 2.0 ml. of antigen and exsanguination after one day of rest on the 13th day. Rabbits can be carried along on "holding doses" and bled over a much longer time to produce a larger amount of antiserum although prolonging the period over which antigen is injected increases the strength and the number of the cross-reactions obtained. Animals which show some but not sufficient response on the 10th day may be given 3 successive daily injections with 2.0 ml. each, following which titers are invariably high enough.

Procuring and preserving sera—Procure the blood by cardiac puncture, place in suitably labeled Petri dishes (15 ml. per dish) and allow to stand at room temperature for 1 hr. Loosen the clot from the dishes with a wooden applicator and store over night in the refrigerator at about 8° C. Remove the serum, clear by centrifugalization, pool with other portions from the same rabbit and preserve by the addition of 0.09 per cent phenolated ether. The preservative is prepared by dissolving phenol crystals in an equal part of ether ("for anesthesia") and should be mixed with the serum by a gently rotatory motion.

DETERMINATION OF SERUM POTENCY

The production of the typical Neufeld reaction is, like other immunological reactions, dependent upon the relative concentrations of antigen and antibody. Within limits, reacting time is also a factor. An antiserum for diagnostic purposes should be standardized in such a way that its potency can be stated on the label in terms which the user can translate into a satisfactory diagnostic technic.

The diagnostic laboratory should have the assurance that an antiserum will react satisfactorily and rapidly in the dosage used with a known concentration of pneumococci. For determining serum potency it is feasible to select a given concentration of a suitable homologous antigen (pneumococci) and determine the minimum dosage of antiserum which will produce a maxi-

num reaction within a period of time not to exceed that routinely used for diagnostic typings. The user of the serum, having been given that information, can apply it to his diagnostic routine by making a rough estimate of the density of pneumococci in materials to be examined followed by dilution of specimens if necessary to keep within the limits defined by the potency of the serum.

The number of pneumococci in a specimen will serve as a measure of the total amount of specific substance only under carefully controlled conditions, but for practical diagnostic purposes it appears to be the only index available prior to determination of the type. The following method of determining this number is suggested:

First manipulate the specimen to render it as homogeneous as possible. A sufficient degree of homogenization can usually be effected by drawing sputum back and forth rapidly into a 2 ml. syringe without an attached needle. Peritoneal washings and broth cultures can be thoroughly mixed by gentle shaking. Place a portion of the prepared specimen of the same volume as that to be used in making Neufeld preparations on a microscope slide together with a small drop of methylene blue and sufficient salt solution to permit the mixture to spread evenly with gentle pressure under the entire area of a cover-slip. Before placing the cover-slip over the mount mix the material thoroughly with a platinum loop. It is important that the mixture remain spread over the entire area covered by the cover-slip and that none be outside of that area. Compute the average number of diplococci per microscopic field (counting the number in the entire depth of each field) after counting several representative fields. The average area of a microscopic field under the oil immersion lens and a 10x ocular lies between 0.015 and 0.02 sq. mm. The areas of cover-slips in common use range from 245 to 625 sq. mm. The number of diplococci in the portion of specimen to be used for Neufeld mounts may then, for practical purposes, be calculated by multiplying the average number per field by a factor obtained by dividing the area of the field into the area of the cover-slip. The values of the factor in round numbers for different sized

cover-slips using an optical system giving 900-1,000 diameters are as follows:

<i>Size of Cover-slip</i>	<i>Factor</i>
18 mm. sq.	20,000
18 mm. diam.	15,000
22 mm. sq.	30,000
22 mm. diam.	25,000
25 mm. sq.	40,000
25 mm. diam.	30,000

A preparation under a 22 mm. square cover-slip showing an average number per field of 10 contains approximately 300,000 diplococci. To provide a satisfactory margin of safety all the diplococci in the preparation must be assumed to be pneumococci of a single undetermined type. The diagnostician must then know that the various sera he uses to determine the type are capable in the dosage used of "quelling" the number of pneumococci found to be present. If he knows the sera lack the necessary potency, the specimen should be diluted to a satisfactory density.

Sera prepared in these laboratories were subjected to serologic analysis by the use of antigen of known density. Mouse-passage strains of pneumococci were used throughout. These were preserved satisfactorily between each series of mouse passages by desiccation under the Flosdorf-Mudd lyophile apparatus. The antigens used for test purposes have been peritoneal washings from mice inoculated with such strains not more than 10 hours prior to autopsy. All tests were made immediately after the washings were obtained to avoid autolysis of the organisms. The approximate density of each antigen was obtained in terms of number of diplococci per ml. by the use of a counting chamber. Antigen of known density and antiserum were mixed in measurable proportions in test tubes and tinged with a small amount of methylene blue in each instance. After standing for 15 minutes at room temperature, a portion of the contents of each tube was placed on a microscope slide and a cover-slip superimposed. Microscopic examination for the characteristic Neufeld reaction and for agglutination was then made immediately. In this way the behavior

TABLE I

"Quellung." Therefore, since the amount of capsular substance to be reacted upon varies from type to type, the zone of dilutions in which agglutination will occur without "Quellung" will also vary and has been observed to do so in our studies. For that reason we consider actual observation of the "Quellung" to be a fundamental step in the quantitative evaluation of serum potency. By arbitrarily choosing a standard density for antigens used in potency tests it is possible to make the determination of potency a simple procedure by testing varying quantities or dilutions of each serum against a standard dose of pneumococci.

For simplicity of application to diagnostic work, potency may be expressed as the smallest amount of a serum which will produce well defined "Quellung" of 1,000,000 homologous pneumococci. Potencies for sera prepared by the short method have been reduced to that basis and are given to the nearest 0.0001 ml. in Table II.

tion of cross-reactions should be as dilute as practicable. The following method at least gives assurance that very weak cross-reactions will be detected.

Check the fresh peritoneal washings from a mouse inoculated not more than 10-12 hours previously against a known homologous antiserum. Shake gently but thoroughly and compute the density of the antigen by the use of a counting chamber. Dilute the antigen until a density of 10,000,000 per ml. is attained. Prepare Neufeld mounts using a 1 mm. loopful of the antigen to each three 5 mm. loopfuls of the serum to be checked. Allow the preparations to stand for 30 minutes before examination and observe at least 5 typical pneumococci for signs of the "Quellung."

The density of antigen used in the above method will yield a single diplococcus in every 3-5 fields under oil-immersion lens if a 22 mm. square cover-slip is used. The examination of less dense preparations routinely in large numbers is too great a strain on the microscopist. Even with prepara-

DETERMINATION OF SERUM SPECIFICITY

For the determination of specificity the fundamental relation between production of a "Quellung" and the ratio of antibody to antigen in the preparation is of paramount importance. For that reason the antigens used for detec-

tions as weak in antigen as these the experienced observer will occasionally detect beginning agglutination or incomplete "Quellung" which should be checked by further dilution of the antigen. We have observed cross-quellung which could not be detected until

TABLE III

the antigen was diluted to a point where not more than one diplococcus could be found to every 20 microscopic fields in the final preparation. In our opinion, these cross-reactions, even though very weak, are of importance and may cloud the issue to the disadvantage of the clinician and his patient.

By ordinary methods we found very few cross-reactions in the sera prepared but when the method was refined to the point described above we were able to detect a larger number of cross-reactions, many of which were exceedingly weak. The cross-reactions we have experienced are reported in Table III.

ADSORPTION OF SERA

Heterologous components detected in sera were removed by adsorption by the following method:

Culture pneumococci of the type to be used for adsorption for 18 hours in the broth previously described. Ordinarily the sedimented pneumococci from 100 ml. culture will completely adsorb heterologous antibodies from 60-70 ml. of serum. Centrifugalize 100 ml. of the broth culture in an angle centrifuge at 3,800 r.p.m. for 20 min. and decant the clear supernatant fluid. Add to each centrifuge tube not more than 70 ml. of serum to be adsorbed. Mix the antigen and serum thoroughly and place in a 37° C. water bath for 2 hr. Stir the mixture at 15 min. intervals. (Overnight adsorption in the refrigerator at 8° C. works equally as well.) After adsorption, centrifugalize the serum-antigen mixtures at 4,000 r.p.m. for 45 min.

and carefully remove and save the supernatant serum. Considerable of the phenol (about 80-90 per cent) is lost from preserved sera in this procedure and should be replaced. After adsorption check the serum carefully to determine that heterologous components have been removed.

DISCUSSION

The method of preparing sera described is based upon the theory that, within limits, the production of antibodies depends more closely upon the frequency of applying an antigenic stimulus than upon the amount of antigen injected. An advantage of the method is the comparative specificity of the serum produced. Probably we have detected as many cross-reactions in the sera prepared as are ordinarily detected in sera prepared by the longer methods. However, we believe the technic described for detecting crosses is more delicate than that usually applied since by its use we have found cross-reactions of low intensity in sera from other laboratories distributed by them as specific. About 75 per cent of the cross-reactions we have detected in our sera have been found only by the use of extremely dilute antigens. Heterologous components of such low intensity are easily adsorbed.

Diagnostic antisera for the Neufeld test are ordinarily grouped to make preliminary observations of the speci-

men. Caution should be used in pooling sera which have been adsorbed, since a certain amount of the soluble specific substance will remain in an adsorbed serum. For instance, a Type 15 serum adsorbed with Type 11 pneumococci should not be pooled with a Type 11 serum since the excess Type 11 soluble substance remaining after adsorption will lower the potency of the homologous serum. It is preferable to pool sera before they have been adsorbed, taking advantage of cross-reactions between closely related types in making the pools.

Careful adsorption studies have been made on sera in which two or more heterologous components were detected. In only one instance was it possible to adsorb out one of these components by the use of the other and even then the process was not reciprocal. In this instance, both heterologous components (for Types 23 and 27) were removable from a Type 32 serum by adsorption with Type 23, but not by adsorption with Type 27 which removed only its homologous cross. No other indication that adsorption could be carried out on a group basis was found.

We have observed that antigens in which some autolysis has taken place may fail to react in a Neufeld test although fresh antigens of the same density show a clear-cut reaction. Further, we have observed, under controlled conditions, inhibition of the Neufeld reaction when the organisms were suspended in the bacteria-free culture medium in which homologous-type pneumococci had been grown. That the substance causing the inhibition was probably specific substance in solution is indicated by the fact that it was not present in the unused culture medium or in a medium in which heterologous-type pneumococci had been grown. These observations extend the relationship between the capsule-swelling antibody and the type-specific agglutinin to include

the homologous precipitin. This is not surprising since Heidelberger and Kabat⁶ appear to have established the identity of the agglutinin with the precipitin. The relationship holds some promise that methods of determining serum potency and specificity can be devised which will be more delicate than those we have used. However, until such time as a quantitative study will permit some correlation between the "Quellung" potency of a serum and its precipitin titer against purified specific substance, antigens for use in checking sera should be prepared in a manner which will insure a reasonable degree of correlation between density and capsular substance together with comparative freedom from specific substance in the suspending medium. Standardization of an antigen on the basis of the number of diplococci in a unit volume will be satisfactory in determining serum potency by the method suggested herein only if the suspending medium contains a minimum amount of specific substance in solution since the production of a "Quellung" is dependent upon the presence of an excess of type-specific antibody over that necessary to induce complete precipitation and agglutination, even though these phenomena may be masked by a prozone.

It has been common practice in some laboratories to check for cross-reactions against related types only. We have detected so many crosses between types hitherto not considered related that we feel it advisable to check each serum against all types. We were unable to demonstrate crosses in rabbit serum prior to immunization of the animals in 5 instances in which this possibility was checked. Confining of tests for specificity to the study of behavior of a serum against only a few types will not be scientifically sound until the complicated antigenic mosaic of the pneumococci has received a thorough analysis.

SUMMARY

A short method for the preparation of diagnostic anti-pneumococcus sera in rabbits is described. Methods for the determination of serum potency and serum specificity are presented. An adsorption technic for the removal of heterologous components is given. The methods described for determining serum potency and specificity are based on experimental studies which suggest that the capsule-swelling antibody is identical with the type-specific agglutinin, and that its agglutinogens must be completely satisfied before the characteristic "Quellung" occurs.

Cleanliness

WHILE various ancient civilizations have left material records of their intelligence in matters of cleanliness for the person, the home, and the city, and in spite of the hygienic regulation of individual and social conduct by religions and dynasties of distant times, the permanent continuous use of

the knowledge of human biology within the structure of civil government is a matter of such recent origin as to be almost contemporary with the present most productive era of the medical sciences. — Haven Emerson, M.D. *Medicine and Civil Government. J.A.M.A.*, Nov. 26, 1938.

Pneumococcus Diagnostic Serum *

ELLIOTT S. ROBINSON, M.D., PH.D., F.A.P.H.A.

Director, Division of Biologic Laboratories, State Department of Public Health, Boston, Mass.

THE typing of pneumococci is rapidly becoming one of the most important functions of laboratories engaged in bacteriological diagnosis; and the successful performance of this function is obviously dependent upon the satisfactory qualities of the diagnostic sera employed. Our experience in Massachusetts made it all too clear that the preparation of satisfactory sera was sometimes difficult and that sera made by even the best laboratories were occasionally something less than ideal. Low potency and lack of specificity were the two stumbling-blocks.

The obvious answer was the setting up of standards for diagnostic sera, and it was hoped that these standards might be made so clearly reasonable and essential that all agencies engaged in the preparation of these sera would gladly adhere to them. Standards established by a federal agency would carry more weight than any proposed by a private organization such as, for example, our Laboratory Section. As the National Institute of Health is empowered by law to regulate the manufacture of biologic products for therapeutic use, a resolution was passed by the Laboratory Section of this Association 2 years ago requesting the National Institute of Health to consider means of regulating

the manufacture of the diagnostic sera.

Since that time there has been much discussion of the various aspects of this problem, and there is every reason to believe that, with the recent issue of Suggested Minimum Requirements for Pneumococcus Typing Serum by the National Institute of Health, we are well on the road to general agreement on the proper solution to it. A description and brief discussion of some of the questions involved may serve to indicate what has been accomplished and what remains to be done.

Certain sera have proved to be unsatisfactory because of low titer, therefore, they must possess a sufficiently high titer; but how high should it be? and how should it be determined? Miss Walter recommended last year a minimum capsular-swelling titer of 1:15 for sera to be used in pools. The tentative recommendation of the National Institute of Health is higher, for it is 1:16 for monovalent sera and 1:8 for pooled sera for all types except Type III. Possibly there is less discrepancy in these standards than would appear at first glance, for the technic described by Miss Walter apparently employs larger amounts of serum in relation to the quantity of sputum.

Inasmuch as the sera will be employed chiefly in the Neufeld capsular swelling method, it would seem better to determine titers by this method than by agglutination. The relative amounts

* Read before the Laboratory Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 28, 1938.

of serum and organism must be specified. As a source of organisms, formalized broth cultures of a turbidity equal to a standard silica suspension are recommended in the National Institute of Health method. Some such suspension must be used, for no laboratory will have at all times sputum samples of all types. I must admit a prejudice in favor of the use of peritoneal exudates from mice, at least for those types which are mouse-virulent, simply because an animal exudate would seem to resemble sputum more closely than does a broth culture.

The specificity of a serum is also of paramount importance. There has been difficulty in the past because certain sera gave reactions with heterologous types of pneumococci more or less frequently. This fault can be recognized by the manufacturer, and remedied by absorption of the serum with organisms of heterologous type, so that it is reasonable to expect and require absolute freedom from cross-reactions.

Because it would be unreasonably laborious to test each specimen against each of the 30 available monovalent sera, it is a common practice to make a preliminary examination with pooled sera. These pooled sera should also conform to the standards suggested for monovalent sera, for otherwise the preliminary examination will be misleading. As the proposed standards apply to pooled sera as well as monovalent ones, this source of error is avoided so long as one refrains from making his own pools from monovalent sera. Indeed, this practice cannot be too strongly discouraged for the process of pooling may dilute at least some of the sera to an undue extent.

Aside from the need for standardized sera, there are other questions worth considering. One of these concerns the best arrangement of types in the various serum pools. It can be shown that if one takes into account the incidence of

the various types, the number of serum-sputum mixtures required for the examination of 1,000 sputa will depend upon how the various sera are combined in pools. From this could be calculated that arrangement of the types in pools which would require the smallest number of serum-sputum mixtures and therefore would require the least amount of effort in the examination of specimens. Unfortunately, however, this optimum arrangement might prove most unsatisfactory in a community where the incidence of the various types did not follow that used in the calculation. Although I am inclined to believe that the allocation of types in pools that is currently employed in the diagnostic sera on the market is not the best, I doubt whether a more permanently satisfactory one can be set up on the basis of our present knowledge of type incidence. Considerable study of type-incidence figures makes it clear that there is so much fluctuation in the prevalence of individual types at different times and places that more figures are required before we try to devise a series of pools more generally useful than the present one. The only point which the available figures make clear to me is that Type I is so generally prevalent that Type I serum is best left out of pools entirely.

In many laboratories it has been customary to examine specimens for the presence of certain types only. For example, most of the typing laboratories in Massachusetts have examined only for the presence of Types I, II, III, V, VII, and VIII. Because some laboratories have been able to assign only 10 to 25 per cent of their specimens to these 6 types we are beginning to feel that they are failing to recognize some organisms of these types. If so, it would be wiser to have all laboratories test their specimens for all types, for they should then be able to get a positive typing on practically every specimen

containing pneumococci. Some of these laboratories do only a few specimens and, as it will be relatively expensive to supply them with sera for all 30 types, we are considering furnishing serum-pools covering all types and monovalent sera for perhaps 6 to 10 of the most common types. When specimens containing pneumococci of the less common types are found, the specimens can be forwarded to a laboratory where all the monovalent sera are available.

Even with such a scheme, pneumococci of undeterminable type will be encountered now and again, for it is generally realized that the present 30 recognized types do not include all the pneumococci there are. It would be desirable if some well equipped laboratory would undertake the study of such strains and solicit the submission of specimens of untypeable pneumococci. Besides increasing our knowledge of this group, such a study would afford a useful check on the general accuracy of pneumococcus typing.

Still another problem to which further attention must be devoted is the finding of two or more types in a single specimen, and the relative importance of each of the types found. Recent papers by Andrewes and by Plummer point out that often one of the types so

found is of more importance than the other, and the general principles involved in deciding this question are fairly clear. Here again more data are needed, and particularly helpful would be figures for the types found in blood cultures and in post-mortem cultures.

CONCLUSIONS

The problems involved in the preparation, standardization, and use of pneumococcus diagnostic sera are gradually being solved. There are still a good many gaps to be filled, and it is only by the collection of further data, based on accurate typing, that progress will be made. The figures most urgently needed are those for type-incidence of pneumococci in sputum and blood cultures, obtained from well scattered geographic areas and covering both typical and atypical pneumonias in the various age groups.

Is the Private Health Agency on the Way Out?*

BLEECKER MARQUETTE, F.A.P.H.A.

*Executive Secretary, Public Health Federation and Anti-Tuberculosis
League, Cincinnati, Ohio*

CHANGE is the order of the day for private health agencies. It is important that they realize this now and prepare themselves for the inevitable. Every private agency must now begin to analyze frankly and as objectively as possible, its functions, accomplishments, and objectives. The change in economic trends—a tendency toward higher taxation, and fewer large fortunes—is certain to increase the difficulty of collecting money to finance private health work. The public will become increasingly critical and insistent upon private health work being done with the highest degree of efficiency on an intelligently organized basis that will permit of neither friction nor duplication.

Three major developments which have taken place recently, will have an effect on the future of voluntary health work. One of these three events was the allotment of Social Security Funds to the U. S. Public Health Service for its own, and for the work of local and state health departments, and in addition, special funds for such purposes as venereal disease and cancer control. These allotments of federal funds have already permitted expansion of tax supported health activities to a limited de-

gree. They represent perhaps the first step in what seems to be the direction we are bound to go, namely the strengthening of tax supported agencies.

The second event was the National Health Conference, held in July. One of the significant recommendations submitted, which has received relatively little publicity because of the overshadowing controversy surrounding medical care plans, was for increased federal funds for state and local public health departments and for hospitals and medical service to the indigent sick. This recommendation seemed to have the almost unanimous approval of delegates attending the epoch-making conference. Perhaps still more to be noted is the fact that the American Medical Association at the September meeting of the House of Delegates in Chicago, concurred in the proposal for more government aid for public health work, mental hygiene education, and care of mental patients, tax supported subsidization of tuberculosis hospitals, more facilities for the care of convalescent patients, and the establishment of a federal department of public health, with its head a member of the Cabinet, group hospitalization, and cash indemnity against sickness.

In view of the readiness with which Congress voted Social Security funds to the U. S. Public Health Service to aid state and local health departments,

* Read before the Public Health Education Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 28, 1938.

and special funds for venereal disease and cancer, it seems almost certain that this part of the National Conference program will go through, if not during the coming year then before many more years have passed. The strong pressure for a Department of Public Health in the Cabinet seems likely to be successful. Obviously, if this program moves forward it will strengthen the tax supported health agency and the tax supported hospital.

Meanwhile, the depression has put a check on the increasing number of large fortunes, and the trend toward higher graduated income and other taxes has reduced the ability of the rich to give to private health work. These are actualities. They are things that are taking place and of which we must take cognizance.

Curiously enough, there is a contrary trend in one field of health activity—namely, that of the private hospital. One of the most extraordinary developments in recent years in this country has been the building up of hospital service plans. Starting only 7 years ago with one small plan in Dallas, Tex., there are today at least 100 large cities which have hospital service insurance actually in successful operation, covering 3,000,000 subscribers. The endorsement of the hospital service idea by the American Medical Association at its meeting of the House of Delegates held last month, can mean only one thing—the hospital service plan is certain of rapid expansion.

In the opinion of the best informed students of the problem, this is bound to have the effect of strengthening the situation of the private hospital. Private hospitals that have been in a precarious financial situation during the depression will find the assurance of payment for service which comes out of the hospital service plan, perhaps their salvation. However, while strengthening one phase of their work and easing their financial

problem, this does not mean that their field of service itself is not likely to be affected. With increased public funds for tax supported hospitals of general, as well as those of special type, it would seem reasonable to believe that more and more of the free patients are destined to go to the public hospitals and more of what have been the part-pay patients to the private hospitals.

It is significant that this very trend toward the build-up of tax supported health and hospital work is due in part to the efforts of private agencies and leaders in voluntary health work to that very end.

Local tuberculosis associations, health councils, nursing organizations, and similar health agencies, public spirited physicians, and laymen all have joined hands with leaders in tax supported agencies to bring about this result. It is an accomplishment of note and a tribute to the unselfishness and to the vision of these men and women. Many of the voluntary agencies are quite ready to place under the microscope the present functions of their agencies and make such adjustments as may be necessary and desirable. Many have already accepted the logical theory that when a tax supported agency can take over its work, the private agency steps out of that field and into another if warranted, or it ceases to operate and these agencies will not be unprepared for the next step.

Let us consider for a moment what some of these changes are likely to be. Hospitals for free patients, clinics, medical service in the homes of the indigent sick now carried on by voluntary agencies are likely to become less necessary as tax supported funds increase. This will not come about in a moment because the lack of adequate service is now so universal that for some time to come there will be needed all of the service of this kind that can be provided by voluntary and tax supported groups combined.

Private agencies will need to devote more of their time and energy toward community planning so that all of our forces may be working together more effectively, with well defined objectives. Their functions will become more and more research, education, building citizen interest and support, pioneering in new fields where the public agency may not be ready to enter, and coördinating public and private programs. This means an increasingly important rôle for the Health Council idea in the local, state, and national fields. Voluntary agencies will continue to have a responsibility for helping to see to it that tax supported funds are well spent and that functions taken over by those agencies are efficiently performed.

There is really no occasion for leaders outside the tax supported health field to have any concern as to the continued importance of their work. It is rather a matter of elasticity and adjustment. Everybody in the public health field knows that so much remains to be done, that we fall so far short of using effectively the instruments that medical science has placed at our disposal for combating disease, that the combined public and volunteer health forces will be needed for years to come. It must all be properly integrated and the private agency must see the changing picture and be ready to modify its rôle.

True, there is reason to believe that the private agency cannot look forward to as great an expansion now as it has had during the past several years. Money will not be so readily available in the form of contributions and donations. There will be less to give, and through the very fact that more is being done out of tax funds there will be more resistance to giving. Therefore, progress in the field of voluntary health agency work will depend less and less upon an increasing amount of money, and more and more upon doing the job as effectively as

possible with what we can get. As private giving becomes harder, donors will demand better organization on our part and the elimination of duplication or even anything that appears like duplication or waste.

We might just as well recognize it now that there must be a complete and frank analysis of the set-up of our private health work in relation to public health activities and its relation to the total program. This will lead, if we follow our course logically and honestly, to the need of some eliminations, some combinations and certainly more centralization of functions. It may be that we are facing the time when we shall have to combine all of our private health work of an educational nature in each local community into one centrally directed organization. Certainly, there is much to be said in favor of the proposal that more can be accomplished with the same amount of money if there is such a centrally directed organization with many subdivisions to do the job of education, program planning, and service.

Are the private agencies on the way out? The answer is—Yes and No. Two classes of agencies may be on the way out, those which have served their purpose or are doing what logically is the responsibility of a tax supported agency, and which therefore ought to cease to exist or change their function, those whose executives fail to see their place logically and to act unselfishly and with vision to change their rôle and adapt themselves to the needs as they exist. An agency which has lost the quality of adjustability has probably lost a considerable degree of usefulness. Those private agencies on the other hand, which are performing an essential fundamental service, which see the picture with clear eyes, which are ready to face the facts as they are, will find a part that they can continue to play usefully for many years to come.

Is There a Place for the Voluntary Health Agency in View of the New Public Health Activities of the Federal Government?*

H. E. KLEINSCHMIDT, M.D., F.A.P.H.A.

*Director of Health Education, National Tuberculosis Association,
New York, N. Y.*

THE question raised in the title of this paper is, in my opinion, the public health equivalent of the larger political question: "Is fascism around the corner?" It openly challenges a democratic principle for which the voluntary health agency has sweat and fought. The challenge is warranted, for never before have such sweeping commitments been made by our federal government as those resulting from the Social Security Act.

A page or two of the history of the voluntary health agency may help to define its position and philosophy. How did it come into being? For almost a century after the birth of our Republic, organized health protection of the people was practically nonexistent. Generally speaking, we, the people, intent on subduing frontiers, passed over lightly our greatest national asset, the health of the people. The Constitution made no specific provision for health protection and legislative bodies showed little initiative in that direction. Driven into

action by sporadic epidemics, governing bodies did, here and there, set up emergency measures, some of which gained permanence and became the nucleus of health departments. Lone pioneers such as Shattuck of Massachusetts and Stephen Smith of New York did stir the state into action, however reluctant, but who will deny that prior to the Civil War public health protection in this country barely existed?

Modern public health activity came into being largely through the stimulation of independent citizen groups. The organization of the tuberculosis movement furnishes an example. Thirty-five years ago when practically no effort was made to curb the endemic tuberculosis, certain leaders, medical and lay, speaking unofficially for the people, determined to create the machinery necessary to combat tuberculosis. They realized that what was necessary were diagnostic facilities, public health nursing, sanatoria, and other expensive services, and that these innovations could be won only by popular demand. Today we see abundant testimony to their faith and vision; the state supervises and carries the major burden of the vast, intricate system of controlling

* Read before the Public Health Education Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 28, 1938.

tuberculosis. It all came about through the pressure of public opinion, organized by voluntary health agencies, who made use of education, demonstration, and social engineering. The job of tuberculosis associations is far from being finished, but they have, thus far, definitely and firmly implanted the principle that the state owes its citizens protection against tuberculosis and at the taxpayer's expense. Venereal disease control, maternal and child hygiene work, public health nursing, and numerous other services now accepted as branches of the health department were similarly initiated by voluntary health groups. There is nothing novel about this practice—it is the American people's way of getting what they want from their government. Theoretically, the Constitution provides all necessary instruments for self-government, but experience has proved them to be unwieldy and necessity has mothered the invention of less cumbersome methods of voicing public demand.

Everyone grants that health protection is the first duty of the state. The ballot is supposed to be the magic wand that makes the state perform according to our wishes, but the ballot alone is utterly incapable of securing for us the blessings offered by modern medicine. Consider this situation: We, the people, value health above all else, yet until recently we have been content with a very mediocre brand of health service for which we were willing to pay no more than about one cent per week per capita. How can we explain this paradox?

In the first place, intelligent desire has not until recently been keenly awake. Desire for an unaccustomed service must be aroused before it is wanted.

Secondly, democracy in action is unwieldy. Between the simple desire of a farmer in Iowa and its fulfillment are uncounted baffles, honorable and other-

wise, to say nothing of trickery and political conniving.

The situation is further complicated by the dizzy speed of medical progress. Laws and practices based on scientific knowledge of today are likely to be obsolete tomorrow. The march of medical knowledge has been so rapid during the past two decades that application in terms of practical measures usually lags far behind.

And, finally, the sciences on which public health is based, particularly medicine, are highly specialized. How should the people know what to ask for? Their official representatives are not usually of the type who can be expected to hand them something for which they do not ask and which they do not themselves fully appreciate or understand.

For these and other reasons we need an informed and organized opinion, expertly led and free from any partisan commitment. The gap between what a self-governing people should have and what they actually get is a wide one which the voluntary health agency strives to close. Such an agency is in effect the conscience and the voice of the people on matters pertaining to public health. The victims of tuberculosis, for example, are greatly in the minority and cannot speak effectively for themselves. Moreover, the potential victims of tuberculosis hardly know what threatens them, but their unfelt needs too must be given voice. The voluntary association formulates these needs, hears these "prayers, spoken and unspoken" and when it expresses them clearly and effectively enough, the state takes heed. The voluntary health agency of the past hardly needs defense.

THE NEW ERA

We are entering a new era—the whole social and political fabric is rapidly undergoing change. In the past we

have thought of our government primarily as constituted authority, austere and commanding even though self-imposed. Pomp and circumstance, uniforms and monumental trappings have fostered this attitude in spite of the fact that we boast of government by the people. Now, in the face of economic distress and enlightened by a broader social vision, we are beginning to think of government as the *service arm* of the people. Government exists not merely to govern, to police us, but to do for us collectively what we cannot do for ourselves singly or in small groups. Parenthetically, I do not believe this newer attitude will revert overnight with the next political turnover, for its roots strike far deeper than current political propaganda. The ball, whose momentum was greatly accelerated by the Social Security Act, will continue to roll along swiftly, which means, among other things, that the protection of public health through governmental agencies is going to expand and become increasingly powerful; and when all that can be done for the protection of public health is being done by government, what further need have we for the voluntary health agency?

More need than ever!—unless we are going to be supinely content to leave to official appointees certain privileges we have cherished in the past. Vast sums of money apportioned to bureaus means a concentration of power in their hands. This increased power need not frighten us; on the contrary, we should take pride in the expansion of service for the common good. But there is no guarantee that the new, expanded bureaucracy* will always be a wise and benevolent one. Bureaucracy is constantly threatened by certain deteriorating influences. One is that the bureau is often tempted to assume arbitrary

power like that of a dictator—it may even become arrogant. At the other pole is the danger that the bureau may become complacent—for governmental procedures tend to become formulated or canalized, and once having worked out a scheme of procedure the bureaucrat is tempted to follow the path of least resistance, and easily falls into a rut. The only safeguard against these and other evils of bureaucracy is eternal vigilance of the people who create the bureaus; and the voluntary health agency stands guard for them.

To think of the voluntary health agency only as a watchdog, however, would be deplorable. Its larger function is to give the people an opportunity to participate, at least in the determination of broad policies. In this country we love and need the soap box, the public forum, the free press. Take away the opportunity to discuss political and social problems, and we move a step nearer the totalitarian state. What government, through its experts, does *to* and *for* the health of the people may be good, but what the people themselves do voluntarily upon their own decision is probably far better. Without the voluntary health agency we are more or less committed to let hired agents do our thinking and planning while we accept submissively the measures they devise for our supposed good.

Experience has shown, too, that a health officer can move forward no faster than the people are willing to follow. And when they do not understand they refuse to follow. Understanding on the part of the masses comes through the tedious process of discussion, persuasion, promotion, and demonstration. How slow, for example, has been the labor of breaking down the prejudice against venereal disease control. But evidently the job of education has been well done, for the American Institute of Public Opinion (which correctly predicted nearly all important

* The terms bureaucracy, bureaucratic, etc., are nowhere in this paper used in a derogatory sense.

elections in recent years) assures us that "Seventy-seven per cent of the people are in favor of free treatment for all venereal disease patients, regardless of their circumstances." Think, therefore, of the voluntary health agency as the people's forum through which citizens become interested, help to shape policies, and willingly coöperate with the technicians we call health workers. Can we afford to lose so valuable a tool of democracy?

The fact that public health procedures are becoming more and more complex is all the more reason why we should preserve this forum. In many instances the scientist (health officer, doctor, administrator) is aware of the technical aspects of a new medical discovery but uncertain, perhaps, as to its social application. For example, a health officer may know about the experience of other countries with the use of BCG in preventing tuberculosis but the question in his mind is "Is this form of vaccination applicable in my district?" He needs a public sounding-board. The man on the street cannot answer him, but a voluntary health agency, representing the people, and which has studied the question not only technically but also socially, can be of great assistance to him in his decision. In fact, without such an agency, he is obliged to make the decision on his own account and thus we surrender to arbitrary governmental power one more item of policy determination.

Finally, those who complacently folded their hands when large sums of money were made available through the Social Security Act for public health development are due for a shock. This money can be put to work in the local community only upon demand. While some funds are available from the federal treasury without strings, most of it is secured only if matched by the local or state treasury. In other words, the people have to *ask* for the service and,

what is more, they must be willing to *share* in the expense. Without a voluntary health agency, how is the local community going to get the full benefit of the Social Security Act? We cannot leave the task alone to officials already harassed by tax-reduction leagues.

Nor can the voluntary health agency yet afford to give up its function of blazing new trails. No matter how well a health department is fortified with money and power, legal restrictions often prevent it from experimenting with, or introducing, a new measure. The voluntary health agency with its greater freedom can often open the way.

FUTURE OF VOLUNTARY AGENCY

Most certainly there is a place for voluntary health agencies! Unoccupied by them, that place will invite the fascist whose creed is efficiency through dictatorial power. But if the voluntary health agency is going to fill that place, some thorough-going house-cleaning is in order; there is furniture in its halls that is obsolete. The tendency of some voluntary health agencies is to cling to projects or services which have pleased the public in the past, long after the need for them has been satisfied. There is other furniture which properly belongs to the official agencies. In principle, enlightened voluntary health agencies have followed the policy of turning over to official agencies such measures as the association has initiated and carried on as a demonstration, once their value has been proved. So long as a service cannot or will not be supplied by government the voluntary health agency, perhaps, has the right to supply it. But there is little excuse for a voluntary health agency clinging to a program of work which is official or technical in nature and which the official agency would carry on if properly asked. A dog-in-the-manger attitude seriously hinders health progress. Now that more abundant funds are available

to health departments, voluntary health agencies which insist upon duplicating activities of the health department will be on the defensive.

The voluntary health agency must also look to its internal organization. Does it truly represent the people and is it qualified to speak authoritatively on public health questions? There are all too many dilettantes on the boards of directors. Serving as an officer because one's psychiatrist has advised that "welfare work will take you out of yourself" may be good treatment for that individual—but not helpful to the cause of public health. When the voluntary health agency is actually led by leaders, spokesmen of the people, responsible citizens who take the time and trouble to understand the project they are promoting, it commands the respect of the people and of the officials and law makers.

To visualize the relationship of official health departments to voluntary health agencies one might compare the health department to the railroad trunk line and the voluntary health agency to the supplementary auto truck service. The railroad is admittedly the carrier of the heavy load, but it runs on rigid tracks along a pre-determined route, a route which leaves some newly developed areas uncovered. The auto service with its greater flexibility and freedom, not bound by strict schedules, is able to penetrate into remote frontiers and byways, inaccessible to the railroad. Each supplements the other. The mistake some voluntary health agencies make is to try to run parallel to, or even in competition with, the official agencies. When the voluntary health agency loses its initiative, imagination, easy mobility, it becomes an obstruction to progress.

Looking into the future one can perhaps visualize the voluntary health agency as a broad, mobile Citizens' Committee on Health. Its function will be

to stand by and to support the health department in every emergency, but it will not assume any of the health department's work. It will not be specially consecrated for all time to any given health problem, but it will be interested in the sum total of health welfare. Yet, it may see fit to place emphasis, as time and opportunity warrant, on whatever detailed problem needs attention. It would be somewhat like the National Guard, able to mobilize its forces quickly, now here, now there, according as the emergency might demand.

A Citizens' Committee on Health, absolutely free of politics, could voice public opinion otherwise throttled by the vested interests. It would help protect the good health officer against manipulation of the "machine" and help to force out the incompetent one. It would make health administration more flexible by furnishing a quick and ready means of voicing public sentiment.

The committee would consist of untrammelled citizens who have taken the trouble to verse themselves in health matters and, therefore, would be regarded as the health conscience and the health voice of a community. Not only would this group be competent to speak but also to act when for any reason the official arm of health fails to function. There is no reason why such a health association could not step into a breach and furnish a specific health service just as is done now, but always with the expectation that in due time the activity would be adopted by the health department.

An objection to the Citizens' Committee on Health is that its aim is too intangible for the ordinary man; the multitude are not interested in public health in the abstract—they will contribute liberally only to a health cause that is dramatized. Tuberculosis, cancer, syphilis—these are fighting words. The broad public health concept lacks dy-

namic power—for some it is no more exciting than a Yorkshire pudding. For national agencies it may be expedient, therefore, to continue the pattern of the past, namely, voluntary agencies for the promotion of specific causes, such as maternal and child hygiene, the prevention of blindness, syphilis control, etc. Such specialism has proved its value in the past. Those chosen to lead voluntary health agencies want and should have specific objectives. Likewise the public is interested in the concrete rather than in the abstract. Of course, health agencies with a specific purpose will have to coöperate with each other; an active alliance and a working give-and-take arrangement is essential. Competition between voluntary health agencies is absurd and suicidal. And all health agencies must, if they wish honestly to promote the cause of health, support the broad program of public health. The National Health Council is a token of the earnest endeavor of national health agencies to work together and we may hope that the new social trend will bring the fine idea back of the National Health Council into full flower.

From the standpoint of local community organization, unification of all voluntary health enterprises seems most sensible. A score of agencies each promoting its specialized work such as the control of syphilis, of cancer, of tuberculosis, means confusion in the public mind and often a deplorable competition between agencies. Were the health department to be similarly dismembered into its several bureaus a storm of protest would arise. Unification of specialized voluntary interests need not, however, be at the sacrifice of the special interests, for a generalized health association may have as many sub-committees as necessary. Cities that have tried the health federation idea can testify to the efficiency of the scheme. Yet, to keep interest in special

fields alive, it may be well to maintain national and state health agencies devoted to some one limited field. Such agencies can afford to employ specialists, produce materials, give expert leadership and so on, all of which would be available to the health committee in the local community when needed.

One other question to which I have no answer is: What shall we do for money? Can the public be interested in the kind of voluntary health agency which does not function by performing charitable deeds but which plans, supports, promotes, and voices demands? Here is a challenge to the health educator. This troubled world now furnishes abundant evidence to show that the populace can be roused to support with fanatic enthusiasm the most vague and absurd concepts. Shall we admit that the same power cannot be invoked to rally them in support of objectives that are sound, even though somewhat abstract?

In summary, I would say that there is a definite place for the voluntary health agency, rightly conceived, in spite of the fact that government promises an expanded public health program. The voluntary health agency is needed not only because it advances us on the road to health but, what is even more important, because it is an instrument of democracy which we need now more than ever before. Self-government is weakened by too much concentration of power in the hands of appointed officials. Freely do we admit that the totalitarian state, unhindered by the interference of citizens' committees operates with efficiency (railroads in Italy run on time) but what Americans appreciate more than all else is freedom—the right to govern themselves. Freedom that is license is a dangerous thing to give into the hands of the people. But freedom that is a self-imposed discipline is the essence of democracy.

The State Public Health Nursing Unit and Its Relation to Special Services*

JANE D. NICHOLSON, R.N.

*Public Health Nursing Consultant, Children's Bureau, U. S.
Department of Labor, Washington, D. C.*

THE efficiency of any complex organization depends primarily upon the provision for administration of its component parts, and particularly for the assignment of responsibilities to each unit or part. Therefore, a discussion of the state public health nursing unit and its relation to the special services requires that consideration be given to these factors. As public health programs are made up of a variety of special programs most of which need public health nursing services, the state public health nursing unit is confronted with the responsibility of promoting and coördinating types of nursing services demanded by these special programs. These programs are directed toward particular diseases or conditions, such as tuberculosis, venereal disease, orthopedic conditions, maternal and child health, and so forth.

The need for nursing services to aid in the development of public health programs was recognized by state departments of health long before provision was made to unify the nursing direction of these services. This is understood, when one recalls that practically all state public health programs

are the result of the development of one service at a time. This gradual development of different special programs, the degree of emphasis placed on each program as a result of special appropriations, and the efforts to incorporate the various special services into a general health program influenced the employment of public health nurses by state departments of health. The increasing numbers of nurses who were employed to participate in these expanding programs ultimately focused attention upon the need for a unit within the state health department that would aid in coördination of the public health nursing activities. Acceptance of the desirability of unifying the nursing direction of state public health nursing services gradually followed.

Considerable variation exists in the present state provisions for the administration and nursing direction of public health nursing services. A review of the existing provisions for state nursing direction of public health nursing activities as compared with the situation in 1931 shows that there are four main types of provisions and that there has been a substantial increase in the establishment of separate divisions or bureaus of public health nursing. According to information published in the November, 1937, issue of the *Health Officer*, the four main types of pro-

* Read before the Public Health Nursing Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 26, 1938.

visions for the administration and nursing direction of public health nursing services in state health departments as of January 1, 1937, were as follows:

A separate bureau or division of public health nursing

A public health nursing unit under central administration

A public health nursing unit under local health administration

A public health nursing unit under a division of maternal and child health

It was also possible to obtain from the U. S. Public Health Service information which to date has not been published. This information shows numerically the present situation according to the four classifications mentioned. It shows that a separate bureau or division of public health nursing is functioning in 26 states, an increase of 17 over the number in 1931. The public health nursing unit functions as part of the central administration in 6 states, an increase of 4 since 1931. The public health nursing unit functions as a part of the unit of local health organization in 5 states, an increase of 2 since 1931. The public health nursing services function as part of the division of maternal and child health in 14 states. This is the only one of the four types of organization that have shown a decrease, a decrease of 10 since 1931.

The trend, therefore, is definitely toward the establishment of a public health nursing unit which will be administratively responsible within state departments of health for the direction and promotion of public health nursing services. The rapid increase in the provisions for separate public health nursing units since 1931 makes it appear obvious that state public health administrators are depending upon the public health nursing units to provide a service which is fundamental in the development of their programs. It naturally follows that under any form of administration the public health

nursing director should work in a close relationship to the directors of the programs of special services and to the director of local health services, for it is the need for adequate public health nursing services to assist in the programs of these divisions that determines the function of the state public health nursing unit in relation to the special services. Each director of these special programs requires an amount and kind of public health nursing that will contribute most to his program. This requirement obligates the state public health nursing unit to perform a function which is different from that of any other administrative unit in state departments of health. This function is to provide a service which is required by different special programs and to coordinate these services into a smooth functioning general health service.

In order that the state public health nursing unit may meet its responsibilities most efficiently, it is essential that the director of a state public health nursing unit participate in the total program planning of a state department of health. Moreover, such participation is particularly important in relation to program planning of each division or bureau that requires public health nursing. Recently, a state director of public health nursing stated that she was not familiar with the entire plans of the state department for the promotion of maternal and child health services. She appreciated the value of being fully informed but, unfortunately, since she had not been requested to participate in making the plan as it related to nursing, she had taken it for granted that the state health officer would not be interested in having her become familiar with the entire plan. The state health officer later expressed surprise that this had not been brought to his attention before. It is through mutual understanding of objectives and plans that the chances for united efforts

are promoted. A state nursing director who understands the needs and implications of public health nursing in the special programs and who is informed as to the availability of needed services, as well as the potentialities for extending adequate nursing services, can contribute valuable assistance in program planning in state departments of health.

It is logical to expect that the staff of the state public health nursing unit will not only give assistance with program planning but will follow this by an advisory service in regard to the nursing phases of each special program.

The assignment of a public health nursing consultant for the purpose of promoting unity of plans and action by the state public health nursing unit and the division which represents the special field for which this consultant is prepared, provides a channel of working relationship between the units or divisions involved. It also tends to lessen a general feeling, on the part of the directors of special programs which require nursing services, that unless definite provisions are made for direct nursing assistance, the nursing services are not always adequate in amount and kinds in a special field. Such state consultative nursing service should be easily and readily available to state directors of special programs, and its influence must permeate the state-wide field nursing services. Locally the consultative nursing service should function through the directors of health programs and the generalized supervising nurse. It should reflect a knowledge and understanding of the whole health program as well as of the accepted principle of rendering public health nursing services on a family-health basis. The degree of success of this consultative service depends in part upon the policies of working relationship, and the extent and ease with which these policies are made to function.

From incomplete reports sent to the U. S. Children's Bureau, it was learned that 66 consultant nurses are functioning in the 51 state and territorial departments of health. The special services represented by this group of 66 consultants are tuberculosis, venereal disease, orthopedics, and maternity. It is known too that some states employ a consultant nurse to function in each of the four special services mentioned and a few states provide more than one consultant nurse in some of the specialties. Therefore it is obvious that the assistance of state nursing consultants has not been provided in all the 51 state and territorial departments of health.

In certain states several generalized supervisors have been provided by the state departments and an effort has been made to include among them certain supervisors with advanced preparation in different specialties, notably tuberculosis, venereal disease, and maternity. The directors of the public health nursing units in some of these states have found that it has not been possible for these state supervisors with preparation in different specialties and with responsibilities for generalized supervisory services, to contribute the necessary amount of assistance in their special types of service. Under this arrangement, conflicts constantly arise between the general supervisory responsibilities on the one hand and the advisory and educational responsibilities which are required for the development of special services.

The rapidly expanding programs directed toward special diseases or conditions, the increase in the numbers of public health nurses who are employed to participate in these programs, the lack of adequate preparation of many of the nurses in these special services, and the acceptance of the principle that efficient public health nursing is best rendered on a family-health basis,

have brought out rather forcefully two points of view as they relate to the special services. On one side, the division directors who are promoting special programs are insistent in their efforts to have specialized nursing assistance, and on the other side the field nurses who are rendering health services from the family point of view are equally desirous of having nursing supervision which reflects an understanding of the entire general health program. There must be found a satisfactory middle path. The needs are—(1) provision for sufficient generalized supervisory nursing services plus (2) provision for educational and consultative nursing services according to the special programs which are being promoted.

The functions of generalized supervising nurses and those of state consultant nurses are interrelated, but they are not interchangeable. The activities of one complement those of the other. The main function of the local generalized supervising nurse is to direct and perfect into a family-health service the performance of local nurses. The demands of family-health services require that attention be given to various special services. Therefore, the preparation of generalized supervisors should include a thorough basic knowledge of the various special services; otherwise it will not be possible for them to assume continuously the responsibility of directing the public health nursing in the various programs.

The main function of state nursing consultants is to assist the director of the state public health nursing unit to interpret special programs of those divisions which require public health nursing, and to develop nursing technics and procedures required by the special programs in order that these may be rendered within the framework of family-health services. The director of a special program is responsible for the

content of the program and for designating the particular places where emphasis is to be placed. State nursing consultants should have a thorough knowledge of public health nursing and advanced preparation in the special services which they represent, otherwise they cannot function with conviction on the public health nursing phases of a particular specialty. The assistance of state consultant nurses should be made available concurrently with the promotion of a special program, provided sufficient generalized supervisors are available to carry the local responsibility and to work with the state consultant.

The program in certain specialized fields, particularly that for the eradication of tuberculosis, has been in operation over a comparatively long period, therefore, the service needs are fairly well understood by generalized supervisors. The best results in the public health nursing phases of tuberculosis programs have been attained, however, where the generalized supervisors have been sufficiently well informed in regard to this clinical specialty so as to meet the daily responsibility for improving and extending the local nursing activities.

Recently, attention has been centered on other programs, notably that for the prevention and correction of crippling conditions. Increased efforts in any program necessitate that consideration be given to the requirements of the program. For example, the program for the prevention and correction of crippling conditions is administered in many states by an official state agency other than the state department of health and, because active participation in this program is an accepted function of public health nursing, the need for satisfactory working relationships between the directors of this special service and the state public health nursing unit is apparent. In programs directed toward crippling conditions, as

in those directed toward other diseases or conditions, the gap between the needs of the program and the needs of the local generalized nurses must be bridged, and by provisions which will promote the efficiency of local and direct nursing services.

In some states, the official agency which is administering the program for crippled children's services has appointed a state consultant nurse. One of the functions of this worker is to promote suitable working relationships between the director of the program and the director of the state public health nursing unit in order that program needs and professional services, as the latter relate to public health nursing, may be correlated and made more effective. In other states, provision has been made for a state orthopedic consultant nurse who functions as a member of the staff of the state public health nursing unit. Under either arrangement the aim is to extend the volume and to improve the quality of public health nursing according to the requirements of the special program.

The increased availability of better prepared field nurses and of adequately prepared generalized public health nursing supervisors, who function in a unit which lends itself satisfactorily to good generalized supervision, may change some of the methods of procedure of state nursing consultants. For the present, however, their function is to render expert educational and consultative services in regard to public health nursing phases of the programs of special services. It is quite conceivable that eventually state consultant nurses will be able to devote more time than is now possible to research in the nursing phases of a particular speciality, and in this way may make even greater contributions toward improving and perfecting public health nursing in special services.

The relation of the state public

health nursing unit to the special service rests then upon certain fundamental factors. One is the administrative provisions within the entire structure of state departments of health. The trend is to establish a separate unit or division of public health nursing that will be responsible administratively for the activities of the unit and for directing and coördinating public health nursing in amounts, kinds, and quality, as needed by special programs. Satisfactory working relationships between the state public health nursing unit and other divisions or units, on the one hand, and other state agencies which require public health nursing for the promotion of their special programs, on the other, naturally must be developed if the state public health nursing unit is to participate in program planning, and, particularly, planning in relation to the special programs, such as tuberculosis, orthopedics, venereal disease, maternal and child health, and so forth.

The assistance of state public health nursing consultants who have had advanced preparation in selected clinical specialties makes possible a continuous educational and consultative service in relation to the nursing phases of special programs. This consultative service on public health nursing phases of the special programs should be available to the state and local directors of health programs and to the local generalized supervising nurses. However, as nursing direction and guidance of public health nursing activities are strengthened through adequate provision for competent generalized supervisors, it seems quite logical that more attention should be given by specialized consultant nurses to intensive and continuous study of the nursing phases of the various services. This type of activity is necessary in order to find new ways to further and to perfect the relation of the public health nursing unit to the special services. The plans of the state

public health nursing unit should reflect a practical but liberal view of what it is possible to accomplish within a given period. They should also reflect a full appreciation of the advisability of preparing and assisting generalized supervising nurses to perform their function

of guiding and perfecting the direct nursing services. In the last analysis, the efficiency of the state public health nursing unit in relation to the special services will be judged by the extent, variety, and quality of the direct nursing services.

Saving Life by Teaching

IN the past there has not been wanting a supply of men and women willing to devote their lives to research into the causes and cure of disease. To devote oneself to educating one's fellows into right ways of living calls for just as much devotion and perhaps even greater self-sacrifice. The research worker has the added incentive that perhaps one day he will be acclaimed as a discoverer, the originator of a new and effective cure. The propagandist

cannot look for any such reward. It is a foible of human nature that when once a man is taught, he likes to feel that he has found it all out for himself.

But it is just as good a thing to save men's lives by teaching them how to save themselves, as it is to discover a new serum which will save them willy-nilly.—James Fenton, M.D., Presidential Address, Society of Medical Officers of Health, Kensington. *J. Roy. San. Inst.*, 59, 5 (Nov.), 1938.

Laboratory Administration as Regards Syphilis Serology*

J. F. MAHONEY, M.D., AND MARGARET R. HARRISON

Senior Surgeon, and Associate Chemist, Venereal Disease Research Laboratory, U. S. Public Health Service, Stapleton, Staten Island, N. Y.

IT is with a feeling of considerable concern that an attempt is made to discuss the subject of serology in syphilis in an abbreviated fashion. The ramifications of the subject are so numerous and so diverse, and the purely technical aspects are so important, that there is a great danger of becoming lost in a maze of detail which would entirely fail to be informative to a group interested in administrative health work. There are, however, several general aspects of the subject which may be scrutinized with profit by the health officer.

On the wave of popular interest recently engendered by the movement looking toward the control of syphilis, the diagnosis of the disease has assumed a new importance. The history of this movement will ultimately be written in the laboratories of the country as surely as the history of an armed conflict is written by those actually engaged in combat. The search for the trail of syphilis now reaches all classes of society, whereas in the none too distant past the level of suspicion seldom reached above the dispensary class. The enactment of laws requiring sero-

logic examination in premarital and prenatal instances places an even more trying burden upon the public health machinery, and renders it imperative that stock be taken of the methods upon which dependence is placed in assuming the added responsibility, and of what can be done to make this foundation more firm and reliable.

The present equipment for the serodiagnosis of syphilis consists of tests based upon two biologic phenomena. The first group is made up of the direct descendants of the original Wassermann, which utilize the complement-fixation principle of Bordet and Gengou as an indicator. The second group represents the practical application of the phenomenon of precipitation or flocculation originally described by Michaelis. Both types of tests are considered to be capable of measuring the same substance in the blood serum, the so-called reagin or Wassermann substance. Both types of tests may be considered as somewhat empirical, since there is at present a lack of precise knowledge as to the nature of the Wassermann substance. There is some evidence that it may be a normal constituent of the blood altered or increased through the agency of spirochetal or disturbed metabolic activity. The basic specificity of the methods,

* Read before the Health Officers Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 26, 1938.

however, gives rise to the belief that the tests are a measure of a true antibody response.

In America there is a group of test procedures bearing the names of their originators, namely the Kahn, Kline, Hinton, and Eagle flocculation methods, and the Kolmer and Eagle complement-fixation methods. There are several other distinctive technical methods sponsored by organizations as represented by the New York State complement-fixation test. All of these procedures, if carefully carried out and interpreted in the light of clinical experience, are capable of guiding an acceptable routine of syphilis work. From a clinical standpoint they do not entirely cover the field, but they represent the best practical application of the present state of the science of serology.

At rather frequent intervals new tests appear in the literature, usually accompanied by the claims that they are equal to the established methods, and have the added and important advantages of simplicity in performance and interpretation. As a rule these procedures, and the claims made for them, may be disregarded by the health department laboratory until such time as they have been thoroughly evaluated against clinical evidence and by comparison of results with more firmly established methods. Generally these tests are based entirely upon some minor technical modification which does not make any significant contribution to the knowledge of serology.

With the flocculation tests special preparation of the antigen, variations in the concentration of the antigen emulsion, and changes in the physical conditions of the test mechanics have the effect of increasing the sensitivity of the procedure. This has given rise to the exclusion or presumptive tests. As a result of the increased sensitivity, the specificity of the tests is interfered

with, and the methods are advocated by their originators as being significant only when frankly negative. The inference is that, if these procedures fail to detect the presence of the Wassermann substance, a more specific, but less sensitive procedure would, in all probability, be negative. Positive findings must be confirmed by other methods. Practically, the methods are used for the purpose of detecting or screening out the bulk of the frankly negative sera, thus reducing the number of specimens which are tested by the more burdensome, but more exact, methods.

It is generally considered that two tests are more satisfactory than one and many clinicians prefer one complement-fixation and one flocculation method. In some laboratories this idea is expanded into a group or battery of tests being carried out on each serum, the final answer being based upon the group of findings, rather than upon the results of any one test. The results of a routine of this type are of questionable advantage over those produced by one or two carefully conducted test procedures. Any superiority in results which may accrue to the use of a battery of tests does not seem to justify the increased requirements in personnel and physical equipment.

It has been previously stated that any of the American methods are capable of producing a high standard of sero-diagnostic results. This assertion must be entirely predicated upon a complete and rigid adherence to the technical precepts advocated by the originator of the method. The maintenance of adequate control of any biologic method requires adherence to prescribed rules and any liberties taken with the technic are ultimately reflected in a decline from the standard of results which the method may be capable of producing.

In this connection it is safe to state that a considerable proportion of the

public is at present being served by methods which do not conform to a standard or sponsored technic. Many of these procedures, especially complement-fixation tests, have been in use for years without any attempt being made toward modernization and many of them are basically incapable of modernization. They produce an indifferent level of results and will continue to do so until replaced by a more adequate method. There can be no greater inducement for accepting a standard procedure than the opportunity which is afforded the laboratory of cross-checking its results with other laboratories utilizing identical methods. Such interlaboratory checking is at present of limited value because so few serologists are content to adopt and adhere to rules prescribed by the several originators of acceptable procedures. Adherence to standard methods means, too, that firmly established improvements can be readily and speedily incorporated, thus keeping the technic abreast of current serologic advance.

Further in this connection there is a definite tendency on the part of operators of serologic technics to alter or modify the method with which they are working. Not infrequently these changes are trivial, representing some whim or fancy of the operator, introduced for personal convenience. Not infrequently, too, technical modifications are forced upon the serologist by failure of administrative officials to provide adequately for the work. In the final analysis, either type of technical deviation from a standard method ultimately works to the detriment of the service rendered the patient whose blood is being tested.

From the administrative standpoint the selection of the personnel charged with the operation of the method is comparable in importance to the selection of a standard method. Technical

pitfalls which may lead to erroneous results are always present, and can be guarded against only by the vigilance of the director of the laboratory and the scientific training and integrity of those actually engaged in the work. The selection of personnel, hampered as it is by employment restrictions and low salary levels, constitutes an important administrative problem. Both basic scientific training and supervised experience are essential. The formal education should consist at least of training in the exact and biological sciences. The supervised experience must be a variable factor, dependent upon the adaptability of each trainee, but it should embrace training in the broad aspects of serology rather than in a single test method.

In the formal type of work which health departments are obliged to do, the method of reporting becomes important. The recommendation of the League of Nations Conference in regard to the use of the terms "Positive," "Doubtful," and "Negative," is probably the most helpful to the average medical man. Many clinicians engaged in active syphilis work desire only the actual readings of the test. The method of the future probably lies between the two; that is, advising the physician of the actual readings together with the originators' interpretation of the degree of positivity displayed. In sections of the country in which there is a prevalence of malaria, the establishment of a consultation service within the health department would seem to be desirable. The interpretation of results into terms of actual syphilis should not be imposed upon the laboratory.

In maintaining a serologic routine at an acceptable level of efficiency, four types of cross-checking appear to be needed. The first consists of an intra-laboratory check between the several methods in use. The second consists of

an inter-laboratory check in which identical methods are used in each laboratory. Access to a clinical material of sufficient size to serve as a clinical check is the third, and the fourth consists of participation in the annual evaluation check which is offered to all state laboratories and in which the findings of each participating laboratory are compared directly with those of the originating serologists. A check system of this kind will tend to display any variations from the expected levels of specificity and sensitivity.

It seems evident that one of the most important functions of state and municipal serologic laboratories must be the assisting of local laboratories to attain high standards of serologic performance. In so doing the state and municipal laboratories must serve the local facilities much as the originating serologists now serve as evaluating agencies to the states. State laboratories should recognize their inability to guide others in a field in which their own performance is not entirely proficient and this type of service may well be delayed until the work in such laboratories has attained a demonstrable level of efficiency which warrants an assumption of the rôle of a measuring stick of satisfactory performances.

A final point of interest to the health officer is the use of serologic methods in surveys and studies designed to determine the incidence of syphilis. The first requisite is that the serologic methods to be used be placed upon a high technical plane and carefully checked against an established control laboratory. Not a few painstaking efforts along this line have been rendered valueless through poor serology, faulty collection and transmission of specimens, and disregard of the clinical background of cases in which positive find-

ings are recorded. A recheck of these cases is essential as is also a clinical survey of a sufficient number to afford an estimate of the influence of co-existing infections. Attention to these details is a prerequisite to the utilization of serologic findings as an index to prevalence.

CONCLUSIONS

Thus, if any message may be left to administrative health officers, it would be that there is available a group of test procedures which represent the best of the present knowledge of serology.

That these methods are sponsored by investigators best situated to improve or to alter their respective tests, in order that the technics may be kept abreast of current thought.

That if a standard or sponsored technic is adopted, it should be carried out as closely as possible in accordance with the recommendations of the author.

That new test procedures should be adopted only after they have been thoroughly tested in clinical work.

That there are in use at the present time a number of outmoded technics which are probably not amenable to modernization, and which are capable of producing only an indifferent standard of results.

That personal modifications introduced into a standard method to suit better the convenience of the operator, or to fit the test more readily to the routine of a laboratory, may well be discouraged.

That the caliber of the work in a state or municipal laboratory should be high enough to serve as a guide to the work being done within the state.

That the results obtained in surveys should be scrutinized carefully as to their value as an index to prevalence.

LEPROSY IN THE UNITED STATES

ONE hears little now about leprosy in the United States, though it is still a scourge in too many parts of the world. Barbarities such as the shipping of unfortunate lepers in boxcars from one state to another, no one state being willing to receive and harbor them, are not heard of any longer, though they have occurred fairly recently and within the recollection of many readers of this *Journal*.

The annual report of our National Leprosarium at Carville, La.,¹ deserves more than casual notice. At the close of the fiscal year, June 30, 1938, there was a smaller number of patients remaining than at any time within the past seven years. This was partly due to the greater number of deaths, of which there were 35 among active cases, and one in a paroled case. Of those who died, 39 per cent had suffered from the disease for 10 years or more. It is encouraging to note that there was a continued lowered admission rate. There were for the year a total of 59 admissions of whom 32 were new patients, the others being absconded patients who returned, paroled cases in whom the disease became reactivated, etc. From the standpoint of nativity, only 9 states were represented by new patients and only 18 are now represented in the hospital. There were during the year 1 admission from Hawaii, 3 from the Philippine Islands, and 1 from Puerto Rico, and a total of 32 from these areas were present in the hospital. There were 20 admissions from 7 foreign countries for the year, making a total of 108 patients in the hospital from 21 foreign countries. As usual, there were more men than women, 243 of the former and 106 of the latter.

One of the main duties of the laboratory is the examination of the patients monthly for the bacillus of leprosy, as it is one of the chief criteria for the consideration of parole. Only after a failure to find the organism every month for a period of one year are the patients allowed to go out on parole. Those showing improvement are examined at monthly intervals while the stationary or retrogressing cases are examined at longer intervals.

An interesting piece of work which is going on is the routine Kolmer, Wassermann, Kahn, and Kline tests on each patient on admission. The laboratory is

attempting to repeat the work of Acosta, of Colombia, who has reported that an extremely large percentage of patients gave a positive complement-fixation test, using an alcoholic extract of a bacillus isolated from the blood stream of a patient as antigen. It is not felt that any report can be given at this time as much more work is required before a decision can be arrived at.

The patients are given every comfort and, while a certain number abscond for one reason or another, there are many others who regard Carville as their home and wish to return. All outgoing mail is sterilized. During the year there were some 135,624 pieces of mail handled. Twenty-six magazines and 9 daily papers are received regularly for the patients' library. For the blind patients there are radios, baseball supplies, soft balls, etc., for their amusement, bought from the patients' benefit fund. There is also a dance orchestra, which is paid from this fund. Altogether, the report seems encouraging.

Just why there is so much public terror over leprosy has never been quite clear. It causes terrible deformities, and was for many years considered incurable. Doubtless, however, some of the unreasoning fear of it has come down from biblical times. It may be said with certainty that syphilis is now much more of a menace to civilization from every standpoint than is leprosy. Is it too much to hope that this *Journal* will be able to report at a time not too far distant that there are only some 500 cases of syphilis in the country?

MARY MALLON

THE death of Mary Mallon, known all over the world as "Typhoid Mary," occurred on Friday, November 11, at the Riverside Hospital, North Brother Island, New York, at the age of 70 years. Her story carries many lessons. For 31 years she has been under the surveillance of the medical authorities through no fault of her own. Many of her last years were spent in a detention hospital to which she was first committed on March 19, 1907. During all these years she was a menace to her fellow men, although entirely innocent of any wrong doing, and like the leper of old, she was branded "Unclean." It is not strange that she was bitter and defiant, and sought legally to escape from detention and to dodge the health authorities, in which she was too often successful, and in this she was reprehensible.

She was the first known typhoid carrier of the United States, and her detection was due to the unusually fine piece of epidemiological work done by George A. Soper, Consulting Engineer, and a Fellow of this Association. At the time of her detection in 1907, she had been the cause of seven outbreaks, with 26 cases of typhoid fever during 7 years. In the course of her career, 30 other cases were believed to be directly, and one probably indirectly, due to her—a total of 57, among whom there were 3 deaths.

There is some reason to go to this extent into the details of her case, since the newspapers very generally have been giving the Germans credit for the discovery of the typhoid fever carrier. The first record we have of typhoid carriers and their danger to the community was given by Horton-Smith, in England, in his Goulstonian Lectures, in 1900. He stressed the danger of the chronic urinary carriers, and called attention to their etiological importance. In November, 1902,

Robert Koch gave his famous address on the subject. At that time there was a great deal of typhoid fever in Southwest Germany, including Trier, the Bavarian Pfalz, and in Alsace-Lorraine—so much so that they were a menace to other parts of the country through migration. Koch pointed out that the chief source of infection to others was the patient and the convalescent, and urged that patients should be made sterile before release. He considered ambulant and abortive cases of great importance. Under his directions bacteriological stations were set up, the first one at Trier, in 1903, under Frosch. The investigation revealed that the intestinal carrier was the most important because the most frequent, and for the first time the suggestion was made by Frosch that the typhoid organism might be capable of leading a prolonged saprophytic existence in the intestine. In 1904 Drigalski proved this hypothesis. His work also showed the significance of atypical typhoid fever in children and went further to establish the dangerous importance of ambulant, abortive and unrecognized cases.

In the last quarter of a century in this country typhoid fever has dropped from a leading position as a cause of death to one of minor importance.* We have been warned by Dublin and Lotka that this brilliant victory over typhoid fever may lull us into a feeling of false security as the disease still causes a great many deaths in certain areas. In the United States it is most prevalent in the larger villages and smaller towns, with less than 10,000 inhabitants. From 1930 to 1932 the rate in these small communities, for whites, was 4.2 per 100,000 against 3.6 for rural areas, and 1.9 for the larger cities. Among the colored, it was 17.5 per 100,000 for small places, 13.6 for rural areas, and 6.3 for the larger cities.

This advice is emphasized by the recent report of endemic typhoid fever in the Department of the Gironde, France. Although the local water supplies, especially in the rural districts, are in many cases unsatisfactory, the zone in which the supplies are best controlled shows the largest number of cases. The inevitable conclusion is that endemic typhoid fever in this district is due to some other factor than the water supply. In the United States unquestionably the purification of the water supply and vaccination have been the two factors which have led to its great reduction.

That the carrier problem is still to be reckoned with is clearly shown by a recent report from the State Department of Health of New York. In 1937, there were 398 typhoid carriers under supervision in the upper part of New York State, exclusive of those in state institutions. This was an increase of 18 over the number for 1936. Twenty-nine of these were discovered through the study of outbreaks and three outbreaks of the disease were traced to previously unrecognized carriers. One has only to glance over the indices of the current journals and note the number of outbreaks due to carriers in institutions as well as the general population.

There is no need at this time and place to go further into the history of Mary Mallon, which has been given in considerable detail and accuracy in the public press. It is good to note that in later years she lost much of her bitterness and lived a fairly contented if necessarily restricted life. She always refused the one operation which might have cured her. When she was declared a carrier she

* For Metropolitan policy holders the death rate for 1935 was 1.1 per 100,000 as compared with 22.1 in 1911. The rate was slightly higher for the general population.

dropped most of her friends and never revealed the story of her life or origin. She evidently found consolation in her religion and all are glad that she is now at perfect peace in the bosom of the church to which she gave her faith and loyalty.

ENGINEERING SERVICE IN HEALTH DEPARTMENTS

FOR the past decade all but four or five of the least populated states have had engineering divisions in their state health departments, while in municipal health departments only one-fourth of the 211 cities with a population of 50,000 or over, employ engineers, and less than 40 per cent of the 37 largest cities of the United States with a population of 250,000 or over, have one or more public health engineers in their health departments.

It is of interest to note, therefore, the announcement appearing elsewhere in this issue that a new organization known as the "Conference of Municipal Public Health Engineers" was formed at the Kansas City meeting. Such an organization should stimulate better engineering procedures through an exchange of ideas and opinions among its members, and by meeting on the day immediately preceding the annual meeting of the American Public Health Association, should increase the membership of the Engineering Section of that body. While the state sanitary engineers are wrestling with standards and fundamentals and attempting to direct engineering programs on a broad scale, the municipal engineers are faced with detail problems of promoting and enforcing specific sanitation programs. The type of problems, therefore, facing these two types of public health engineers, while fundamentally similar, are actually quite different.

There seems to be quite a definite need for this Conference of Municipal Health Engineers and we wish them all success with their new organization.

PUBLIC HEALTH EDUCATION*

Giving Information about Information—Gradually we are making it easier for our constituencies to get information about the information we have on tap.

Latest to progress is the N.O.P.H.N. Reprints from their magazine now come with this legend in small type at the top of the first page (with different prices according to size of reprint):

"Price 20c. One copy free to members of N.O.P.H.N."

Anyone seeing one of those reprints need not hesitate about the price to send for a copy. And every reprint carries a gentle reminder of a membership privilege.

Many advertisers, especially those asking for mail responses, weigh every detail which might lead a reader to hesitate even slightly before writing or sending in a coupon.

In the health field every pamphlet or folder, every mimeographed sheet we would like people to ask for, might well carry the price, or "a copy free upon request." Thus every copy carries its invitation to any accidental reader anywhere. State publications might add: "... in this state" or "... in this city."

Let's Do Something about It—The problem is stated in *Safety Education* (National Safety Council, Chicago):

The Education Division wishes to fill all requests for safety material in so far as

possible. It is difficult, however, to respond to letters that ask simply for "safety material," since so many different kinds are published. Persons writing for material are asked to state specifically what is wanted, so that their requests may be filled promptly and correctly. Lists of available material may be obtained from the Education Division.

Probably all sources of health information receive many similar indefinite requests.

Whenever writers, teachers, editors, public health workers, and others, print, mimeograph, or speak, and mention an address as a source for health education "material" could we not urge that those who use the information tell who they are, what use they have for the material, whether they are teachers or students or what, and *give the date when any event or time of use is dated.*

Will the compilers of printed or mimeographed lists of sources please include some such statement?

How to Prepare Sound-film-strips—Or, talking slide films as they are also called. Full working details on preparing the script and selecting the photographs are given in "Preparing Sound Film Strips," by C. R. Thomas. *Educational Screen*, 64 E. Lake St., Chicago, Ill. Oct., 1938. 25 cents. (If you go in for projection material, or for visual education in the schools you will wish to subscribe to *Educational Screen* at \$2.00 a year.)

No quotation from the article would be worth while. The whole of it needs to be read and studied.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

"Please Send Me"—An article by C. R. Read in *Bulletin*, Am. Society

for Control of Cancer, 1250 6th Ave., New York, N. Y. Nov., 1938.

From September of 1935 to September, 1938, 49,006 letters were received, a large proportion of them requests for information, each one with overtones of fear or despair or hope. None of these letters goes unanswered. Where general data on cancer are requested, standard pamphlets are sent out at once. If the request is for medical help, as it often is, the writer is promptly referred to the local chairman of the society or a member of the cancer committee of the State Medical Society. When the letter outlines a "sure and positive cure," the society explains that it has no authority under its articles of incorporation to test such methods of therapy and refers the writer to the local medical society.

What people ask for, and the varied uses for the answers, are described.

Collective Thinking—A group of health workers is gathered to consider possible uses of some new graphic material.

After an explanation of the material and its availability, the question is asked: "What use can be made of it?" or "Dr. Jones, what is your idea as to how to use this material?" Others volunteer or are called upon. One starts with a lay audience. Someone else suggests use with some professional group. Another person proposes a plan for promotion or advertising the material. Then back to a professional group. And the hop, skip, and jump of individualistic thinking continues.

In contrast: the chairman asks what professional health, nursing, and medical groups might be interested?

Then how and where would they be reached, and how should the graphic material be made up. That brings collective thinking, all members of the group concentrating for a few minutes on that specific problem.

Then the chairman asks if the material would be usable with lay groups. After a quick affirmative the questions of how and where are taken up. The

collective thinking thus concentrated on one phase of a problem brings rich results.

All of this disposed of, the chairman inquires as to the promotion of the uses thought to be acceptable. And time is given for any overlooked angle.

Thus time is saved and group thinking has registered various uses, and there has been opportunity for all to express their opinions on the ideas submitted.

Is not collective thinking better than the hop, skip, and jump technic?

For Newspaper Beginners—"50 Hints for Obtaining Newspaper Publicity," by National Tuberculosis Assn., and probably available free through state and local tuberculosis associations.

Elementary instructions are stated quite concisely in 50 paragraphs. All are quite according to Hoyle, except that No. 1 sets quite a task for the newspaper man.

"Get acquainted with reporters, departmental editors, *et al.* Ask them for suggestions as to the type of material they want, the manner in which they want it prepared, and when they must have it."

We have had to listen too often to newspaper men agonizing over the effort to explain to uninformed audiences what the editor wants and how it should be prepared.

Would it not be simpler and easier for both parties for the tuberculosis worker to take the copy, the information, or the ideas he has to the editor, and ask what to do about that specific material? (Especially in view of the publicity ideas and ready made copy supplied to many locals by the state associations.)

On Factory Bulletin Boards—A fairly common type of poster bulletin board has been widely introduced for displaying safety warnings. The Chicago Tuberculosis Institute (360 W.

HOW ARE YOU?

- * Just how well are you? Are you physically able to enjoy the winter months to follow?
- * Now is the opportune time for that fall check-up. Regardless of age or occupation everyone should have a complete health appraisal.
- * See your doctor now! Have a thorough physical examination including a chest X-Ray and a blood test.
- * This will facilitate the correction of minor defects and abnormalities before serious illness results.

THE TUBERCULOSIS INSTITUTE
OF
CHICAGO AND COOK COUNTY
200 N. MICHIGAN AVE., CHICAGO

Christmas Health Seals Support Our Work

Michigan Ave.) provides a monthly letter size sheet headed "Health Flashes." Some 7,850 copies go to about 815 industries.

Another sheet, "Man-Power," "health news for industrial management," goes to executives and foremen, 3,100 copies a month.

This service has run continuously since August, 1930. Both sheets are illustrated on this page.

Medical Supplements to Newspapers—That we do not get to see much material that is issued gets emphasis from the quotation below from *Journal of A.M.A.* (Nov. 12, 1938). These tabloids did not come our way for mention in the *Journal* and display at the next convention.

Two county societies have recently collaborated in the publication of medical supplements in their local newspapers. On October 25 the Nassau County Medical Society, Mineola, N. Y., published a health section of 48 pages in the *Nassau Daily Review-Star* and on October 30 the Wayne County Medical Society, Detroit, published its second annual medical supplement in the *Detroit Free Press*. Both supplements were profusely

FACTS ABOUT HEALTH AND SICKNESS

"Every year 70 million sick persons lose more than one billion days from work."

"Workers in industry have a life expectancy approximately eight years less than non-industrial workers."

"For respiratory tuberculosis, the death rate among unskilled workers is seven times as high as for professional workers."

"In 27 iron and steel towns, the death rate from pneumonia is two-thirds greater than in the United States as a whole."

"A million workers are exposed to the hazards of silicosis."

"Health supervision is inadequate in most industrial plants employing 500 or less workers; representing some 62% of the working population."

"On the average day of the year, there are four or more million persons who are temporarily or permanently disabled by illness, - unable to work, attend school or pursue their customary activities."

"Among gainful workers, there are on the average probably ten days of sickness disability - in the course of a year - but these disabilities range from a day, a month, a year, to a lifetime."

(Reprinted from "The Unserviced Millions" by Helen Hall & Paul Kelllogg in Sept. (1933) Survey Graphic).

A HEALTH SERVICE FOR YOU

In the interests of better industrial health The Tuberculosis Institute of Chicago and Cook County has enlarged its Speaker's Bureau to include special health programs for industrial employers and employees.

Motion pictures, silent and sound, graphically describing many phases of the tuberculosis problem are available upon request. Lectures, too, embodying important facts about tuberculosis and other industrial health problems will be presented to your group by outstanding public health authorities.

These two services are available, free of charge. We suggest you write for descriptive folder. Please send requests to Speaker's Bureau, The Tuberculosis Institute of Chicago and Cook County, 360 North Michigan Boulevard, Chicago.

EARLY DIAGNOSIS AND THE JOB

(Excerpt from article by Holland Hansen, Director, Rehabilitation Service, National Tuberculosis Ass'n.)

"Tuberculosis should no longer be thought of as necessarily fatal or permanently disabling. When discovered in its earliest stages it is definitely curable."

"In the employment market, wages and salaries are paid not according to need, but in recognition of what the applicant has to sell."

"Early diagnosis is a major contribution to the rehabilitation of the tuberculous because it lessens the number of occupational cripples."

CHRISTMAS SEALS PAY FOR OUR WORK

illustrated and the editorial content was of a high order. Both were published in tabloid form with original front-page layouts, the Nassau society using an interesting arrangement of photographs and the Wayne County society using an original drawing. Not only were the activities and functions of the local societies and the American Medical Association described in both supplements but a wide variety of interesting articles on all phases of medicine and health were used. Such supplements, properly prepared—as these two were—provide an excellent medium of public education in matters vital to health of the individual.

How Bulletins or House Organs Are Mailed—The paragraphs below indicate a diversity in practice which suggests that a detailed inquiry might be worth while.

Why are certain practices followed? When is one method better than another? If second-class privileges are good for some, how may others get the same privilege when desired?

Could a committee of Public Health Education Section make the study? It would not be much of a job.

The paragraphs which follow cover a part of the periodicals received by this department. It ignores those issued by national agencies, and those distributed under frank through coöperation with the U.S.P.H.S. Both printed and mimeographed issues are included.

Among those which send their monthly or weekly bulletins by second-class mail: state departments of Connecticut, New Jersey, New York, Ohio, Virginia.

Mailing bulletins under permit number, Sec. 526, P. L. and R.: California Industrial Accident Commission, West Virginia Tuberculosis and Health Assn., Iowa State Dept., Colorado Springs Dept.

Paying straight one and one-half cent postage: National Health Library, and city departments of Albany (using stamped envelopes), Belmont (Mass.), New York, Rochester.

Using postal meter: West Virginia State Dept.

The following do not use envelopes or wrappers: West Virginia Association, Belmont City Dept., state departments of Connecticut, Iowa, New Jersey.

Of the above group: Belmont fastens the fold with a sticker, Iowa fastens with a stamp, using one cent postage a copy, Connecticut, West Virginia, and New Jersey mail with pages unfastened.

Stencils are used in addressing all bulletins listed above, except Albany and Virginia, which are typewritten.

Health Education in 30 Cities of 250,000—The Department of Health of New York City has announced a 3 year project in neighborhood health education activities.

Philip S. Broughton, who conducted the recent nation-wide syphilis educational campaign for the U. S. Public Health Service under Surgeon General Thomas Parran, will head the new project.

The new project will be closely identified with the work of the department's Bureaus of Public Health Education and District Health Administration, and will be guided by

an Advisory Committee of which Commissioner Rice is chairman and which includes outstanding leaders in the public health field.

Mr. Broughton, until he was appointed to this new post, was in charge of the Office of Health Education of the U.S.P.H.S. Previously he had been in various governmental positions. Prior to entering government service in 1933, Mr. Broughton was on the teaching staff of the Department of Government at Dartmouth College for 2 years; he held a Cowles Fellowship in government at Yale University; he taught at the College of the Pacific, Stockton, Calif., following his graduation from the University of California in 1927. He is 34 years old, married, and has two children.

Two health centers of divergent characteristics will be chosen as testing grounds for conducting district health education and for establishing and extending health education methods which will be generally applicable to all districts. These centers also will be used for training of personnel within the district, as headquarters for health education seminar and discussion groups, and for observation of health officers from other districts.

Headquarters' personnel for whom a period of district observation and activity seemed useful could be brought to the training districts for brief periods, especially those whose work, although conducted at headquarters, has a particular relationship to district activities.

Assistance and guidance will be given to district health officers in developing their local health programs, of which the following procedures are indicative:

1. Spreading information to the leading people of the neighborhood about special district health problems, what scientific medicine offers for their solution—how they can help other people to understand these matters.
2. Producing health education material needed locally.
3. Organizing periods of intensive district education on important health subjects.
4. Visiting physicians to acquaint them with health district resources and to ascertain district health education problems known to physicians on which they may wish assistance or feel that community work is needed.
5. Stimulating the use of the most effective methods of individual education.
6. Keeping the District Health Education Committee and the School Health Education Committee informed regarding health education needs and activities and utilizing their assistance.
7. Helping in the health education of patients and their families.

8. Assisting in organizing meetings and other educational activities for physicians.

9. Supplying teachers with approved health education materials.

10. Providing a district information service on health education.

11. Assisting in the building and maintenance of a health education reference file for health center and other district workers.

This new project will utilize

... the Health Department's rapidly developing plan of District Health Administration of 30 health districts, each with a population of about 250,000 and each eventually to have the full-time service of a qualified district health officer responsible for the public health administration within the area. In 9 of these district new buildings are in use and 4 additional units are under construction.

Reaching 25,000,000 People —

How exhibits are used to that end is reviewed briefly in "Looking at Health," by Thomas G. Hull, exhibit specialist of the A.M.A. *Hygeia*, 535 N. Dearborn St., Chicago, Ill. April, 1938. 25 cents.

More than 25,000,000 people annually attend state and county fairs, community expositions and neighborhood carnivals in this country. In one of those years when a world's fair occurs, as it does at irregular intervals, millions more are added to the attendance record. But whether 800 persons go to an obscure county fair, or 800,000 to a state fair, or 8,000,000 to a world's fair, all of them go to see what they can see. Some are bent on pleasure alone; some are looking for specific information, but all of them are looking. Such ready-made audiences in receptive moods offer opportunities of which health educators have been taking advantage for many years.

There are three methods of absorbing health information—by listening, reading, and just looking. The lecturer, whether from the platform or over the radio, employs one method; the magazine, book or pamphlet offers a second means; the exhibit, if it is properly presented, employs all three.

Looking at a well prepared exhibit is a delight and repays a visitor for his time and trouble in coming. An especially attractive exhibit will bring a person back time and again just for the thrill he receives from looking. The message that is presented, of course, must be readily understandable, without a great deal of study and wondering.

Listening to the demonstrator tell about the exhibit adds much both to the enjoyment and to the knowledge of the visitor. The task of demonstrating is a difficult one, requiring aptitude and stamina. Many mediocre exhibits have been made outstanding successes because of the initiative of the demonstrator. More than once has such a person "stolen the show."

Reading the written material that accompanies the exhibit gives still further details of information. The more intriguing the exhibit, the more will the visitor read labels and legends, seeking out every scrap of information obtainable. Then there are those industrious persons who come with notebooks and pencils, spending an hour or more in the exhibit copying everything. For their benefit the American Medical Association introduced and often uses "exposition files" with visual indexes. So popular were these files at A Century of Progress Exposition in Chicago that the first set was worn out and had to be replaced before the summer was half over.

The visual impression gained from "looking" is the primary factor in the exhibit. It is gained without mental effort, and it is lasting. The show is a success or a failure according to the result of the visual impression.

A Talking Slide Film — "The Nurse's Responsibility in Saving Sight" is offered by National Society for Prevention of Blindness, 50 W. 50th St., New York, N. Y.

Emphasis is placed throughout upon the close integration of the eye health program with the general health activities common to all fields of nursing. The health of the eye is presented from prenatal life to old age.

The scientific facts on which eye health is based are correlated with the suggested program. The Society presents it in the belief that schools of nursing, staff education groups in hospitals and public health agencies, and nurses' associations will find it a valuable supplement to other teaching materials.

As an educational device the talking slide film has many advantages. "The Nurse's Responsibility in Saving Sight" consists of 120 still pictures on a film strip synchronized with a double-faced record carrying a lecture addressed to nurses. As the film strip and record are completely separate, they may be interrupted at any point to permit discussion—thus giving the advantages of a series of slides with the addition of a lecture in the

form of a phonographic narrative. Running time is 30 minutes.

The complete production—film and record—can be purchased from the National Society for the Prevention of Blindness at \$5.00, plus transportation. It is also available for rent at \$2.25 per week, plus transportation costs.

The National Society explains the talking slide projector:

These projectors are made by several manufacturers. Models range in price from about \$70 to \$130 according to the number and type of lenses, size of screen and of audience.

Arrangements can be made to rent the various models of projectors for periods of one month or more through the office of the National Society for Prevention of Blindness.

Western Union Telegraph Company operates a rental service in many large cities. For details on this service communicate with your local Western Union.

Many commercial firms have these machines and will lend them to non-profit agencies. Firms likely to have the machine include automobile dealers, oil distributors, large manufacturing concerns, distributors of some food products, and some utilities. A number of state health departments also have projectors.

Adult Education as It Is—And as adult education may become, is studied in a series of small volumes issued by American Association for Adult Education, 60 E. 42d St., New York, N. Y. Financed by Carnegie Corporation of New York, these books are distributed free to members of A.A.A.E.

A better understanding of adult education in general may further health education in particular among adults. The first step is to get acquainted with the Association and its *Journal of Adult Education*.

DATES AHEAD

Local and national dates, past and present, special days and events of many kinds offer elements for freshening your own events. Dates may bring a bit of color to a story you need to write or to speak.

Then we want to help other health groups with their special days, or at least we want to avoid planning competitive events.

Birthday of Benjamin Franklin, January 17, 1706.

Birthday of Robert E. Lee, January 19, 1807.

Child Labor Week-End, January 23-29.

First Free School Dental Clinic in America organized January 22, 1907.

Birthday of President Roosevelt, January 30, 1882.

Third National Social Hygiene Day, February 1.

A "Social Hygiene Day Kit" is offered free to agencies sponsoring community or group meetings. Includes program suggestions; press book with news stories, editorials, et cetera; talks and spot announcements for radio; lists of available literature, films, exhibits, and other materials. Slogan: "Guard Against Syphilis!" Address: American Social Hygiene Association, 50 West 50th Street, New York, N. Y.

First modern hospital opened in Philadelphia, February 10, 1752.

Birthday of Daniel Boone, February 11, 1735.

Birthday of Abraham Lincoln, February 12, 1809.

Race Relations Day, February 12. Address: Federal Council of Churches, 297 4th Avenue, New York, N. Y.

St. Valentine's Day, February 14.

1939 Early Diagnosis Campaign is outlined in "Step by Step," an 8 page folder. "An Appeal to Leaders," a 12 page pamphlet, states the case for finding early cases, and the groups most important to reach. Two small, popular folders have effectively simple cover pages. In contrast, two posters have numerous kinds of lettering and other devices in assorted colors. For copies see state and local tuberculosis associations.

"Self-Help In Health" and "Use Your Health Services" were slogans for the recent Health Week in England.

BOOKS AND REPORTS

Sulphanilamide Therapy of Bacterial Infections — *By Ralph R. Mellon, M.D., Paul Gross, M.D., and Frank B. Cooper, M.S. Springfield, Mo.: Thomas, 1938. 398 pp. Price, \$4.00.*

This book clearly expresses in logical sequence the vast amount of material dealing with sulfonamide therapy in experimental and human infections. Especial reference is made to the diseases due to hemolytic streptococci, pneumococci, meningococci and gonococci.

There is an excellent review of the earlier literature of the chemistry and pharmacology of the sulfonamide compounds and their experimental and clinical employment. The author's experiments dealing with the bacteriostatic effect of sulfanilamide *in vitro*, therapeutic results with sulfonamide compounds on streptococcal and pneumococcal infection in laboratory animals, and limited clinical experience with these compounds in pneumonia and streptococcal meningitis are presented. The mechanism of action of sulfonamide compounds and the mobilization of the defense factors of the host, are discussed. General chemotherapeutic consideration and the criteria of therapeutic efficiency as determined by host factors, experimental conditions and the variability of the infective agent, are considered. As addenda, photo-sensitization and the allergic-like action of sulfanilamide, control of sulphemoglobinemia, elixir of sulfanilamide, (Massengill), streptococcal and filtrable virus infections, and sulfonamide compounds, and marrow culture medium for

bacteriostasis tests in chemotherapeutic studies are given.

There is an extensive bibliography of 305 references to American and foreign literature. Dealing with a highly technical subject, it is presented in fascinating style. It should serve as an excellent reference for anyone wishing to get quickly a comprehensive idea of these timely and important therapeutic agents.

JOHN P. WENTWORTH

Essentials of Medicine—*By Charles P. Emerson, M.D., and Nellie Gates Brown, R.N. (13th ed.) Philadelphia: Lippincott, 1938. 845 pp. Price, \$3.00.*

When a book has reached its 13th edition it has proved its worth and there is little to be said of it further than to announce a new edition with the improvements and additions. This 13th edition has been rewritten, and as the authors say, it is essentially new.

The book is intended primarily for nurses, and the rewriting has been done in accordance with the suggestions contained in the *Curriculum Guide for Schools of Nursing*, of the National League of Nursing Education.

The Introduction to Medical Nursing has been considerably enlarged and brought up to date. Public health and sanitation, clinical psychology, and clinical sociology are considered. As the book contains only some 806 pages of text, duodecimo, it is evident that it is condensed, but the authors state that they have been careful to avoid the dangers and evils of "boiling down" a textbook of general medicine.

We believe that the authors have carried out their announced plan with

success. The senior author, Dr. Emerson, died September 26, 1938, after the receipt of the book for review. On page 658 is found an error which is already too common with students, "epidermiology" for epidemiology. The printing and make-up are excellent.

MAZÏCK P. RAVENEL

Parasitology: With Special Reference to Man and Domesticated Animals—By Robert Hegner, Ph.D., Francis M. Root, Ph.D., Donald L. Augustine, Sc.D., and Clay G. Huff, Sc.D. New York: Appleton-Century, 1938. 812 pp. Price, \$7.00.

This book is a second edition of *Animal Parasitology*, by Hegner, Root, and Augustine. It deals with the animal parasites of man and domesticated animals with special emphasis on those which parasitize man. Dr. Huff has revised the section on arthropods originally written by the late Francis M. Root. No radical departures have been made from the previous edition, but revisions have been made throughout bringing the subject matter up to date. A number of new illustrations have also been added. The book leans rather to the zoological side of the subject but emphasizes host-parasite relations and in this way brings in considerable material in connection with the pathology and clinical symptoms produced by parasites. Treatment, prevention, and control are also considered. There is an extensive bibliography but one is disappointed to find that many of the references in the text are not included.

A number of points indicate that the revision was not as complete as it might have been. For instance, under the subject of malaria no mention is made of the parasite which many protozoölogists have designated *Plasmodium ovale*. The penetration of the sporozoite directly into red cells is stated as the apparent fate of this form despite the fact that many recent observations

indicate that some other procedure takes place. An obsolete and cumbersome method of staining thick blood films is given. In connection with kala-azar the more potent pentavalent antimony preparations are not mentioned in treatment. Neither is hexylresorcinol mentioned in the treatment of ascaris. One is also somewhat disappointed to find many typographical errors in a second edition. The book remains, however, as it was in the first edition, one of the best text and reference books in the English language on the animal parasites of man. HENRY E. MELENEY

Public Administration Organizations: A Directory, 1938-1939—1313 East 60th St., Chicago: Public Administration Service. 190 pp. Price, \$1.50.

What each of 558 national organizations do, and which of them do this or that, are two features of this usable and useful reference book. It is the fourth biennial edition of the *Directory* of voluntary organizations working in the field of public administration, or organizations which affect public administration. The range, from Accounting to Weights and Measures Regulation, includes Child Health, Housing, Mental Hygiene, Milk and Food Inspection, Public Health (43 nationals), Physical Education, etc., etc.

Listed, but not described or classified, are 1,342 state groups, 80 regional, and 87 Canadian. EVART G. ROUTZAHN

Mental Health Through Education—By W. Carson Ryan. New York: Commonwealth Fund, 1938. 315 pp. Price, \$1.50.

In his choice of a title for his book, the author proclaims his faith that one of the major goals of all education should be the development of personalities characterized by mental health. The vision of educators should not, then, be narrowly limited to the appli-

cation of the mental hygiene approach only to those pupils who are seriously maladjusted. The educational program should be radically revised so that the principles of mental health may permeate the whole educational system for the purpose of developing and maintaining the mental health of the educational staff as well as of *all* the pupils.

After briefly analyzing many of the aspects of educational programs which remain uninfluenced by the accumulated knowledge of personality development and growth and describing many progressive developments in a variety of fields which may have constructive suggestions for educators, the author lists the following as essential first steps in achieving mental health through education:

1. A re-facing of the educational task by school leaders and the general public, whereby education will endeavor to meet more fundamental human needs than those ordinarily dealt with in the conventional school.

2. Insistence upon a better "emotional climate" for schools with more appropriate school buildings, more wholesome classroom situations, and a more satisfying teacher-child relationship.

3. A radical change in the methods of selection and preparation of teachers and administrators that will make teacher-education more like the training of social workers, with emphasis on cultural resourcefulness, understanding of the sciences underlying behavior, and direct contacts with children.

4. Provision of an enriched and flexible school curriculum, to be determined in each case by the needs and interests of individual human beings and the group, and giving major attention to the arts and other creative activities rather than to traditional subject matter.

5. A new type of school administration, with a mental hygiene viewpoint, that emphasizes optimum growth and development of human beings rather than the mechanics of control, as at present.

6. Extension, as rapidly as possible, of the service of the visiting teacher or a similarly qualified worker to all communities, and the establishment of sufficient child guidance clinics or similar facilities to meet the needs of all children.

7. A closer rapprochement of the family and

the school in mental hygiene activities, and extension of the nursery schools to reach all the families in the community.

8. Active collaboration by the school with community forces working for mental health (with understanding of and consideration for economic and social conditions, religion and religious organizations, racial and cultural influences, play and recreation, motion pictures and radio, and health and biological research).

This book should be of interest to all those who are concerned with education and with the influence of educational programs on the personalities of teachers and pupils. CLARA BASSETT

Maternity Services — By Dame Janet Campbell. London: Faber & Faber, 1937. 56 pp. Price, \$.50.

In this clearly written booklet Dr. Campbell has set forth in order the problem which confronts us in maternal mortality, has outlined its various causes and prospects of preventability. She has sketched the maternity services available in England stressing particularly antenatal care and care at the time of confinement. She states that from the standpoint of morbidity better postnatal care should be provided preferably through special women's clinics. From a wealth of experience the author discusses the midwife problem in England. She gives suggestions for training and qualifications, and sets up the standards for the trained nurse-midwife or obstetric nurse. The responsibility of local authorities is clearly set forth. A list of references to the British material is given at the end. Anyone who wishes to get a clear picture of the present status of maternity services in Great Britain should certainly have access to this pamphlet.

RICHARD A. BOLT

Physical and Health Education— By Helen Norman Smith and Helen Leslie Coops. New York: American Book Co., 1938. 323 pp. Price, \$2.25.

The authors begin wisely in drawing heavily upon various authentic sources in an attempt to establish definitions of terms subsequently used in the book. The subject matter presented also covers basic meanings, curriculum development, physical education and its related activities, health service, health instruction, healthful school living, and a particularly good section on sources of material and reference readings.

In including, with suggested reservations as to their use, the Baldwin-Wood Weight-Height-Age tables on pages 70-71, the authors say incorrectly, "These charts are reprinted by permission of the American Public Health Association (formerly The American Child Health Association)."

This book is an excellent one to help those who have the responsibility for building up school programs, personnel, and administration, as well as for those, be they specialists or non-specialists, actually engaged in the fields of physical and/or health education. The authors cover a wide range of material. The book is so organized as to lend itself to ready reference. W. W. PETER

Medical and Legal Aspects of Tuberculosis as an Occupational Disease and as an Occupational Injury—By Mary Graham Mack. *New York: National Tuberculosis Association, 1938.* 188 pp. Price, \$1.00.

As pointed out by Dr. Kendall Emerson in a preface to this valuable study, the purpose of the volume is not to present an exhaustive summary of all cases bearing upon tuberculosis as an occupational disease or an industrial injury or accident, but to present representative decisions with discussion of the various problems involved so that litigants, lawyers, social workers, courts, and boards of various kinds may be able to refer readily to citations bearing upon questions in point.

Both as a reference work and as a

guide to the solution of a difficult and somewhat moot problem, this book should prove of general value. It might have been improved somewhat by including all court decisions in one section, with more complete legal citations; and all administrative rulings in another, since the courts rather than quasi-judicial bodies always have the final say in legal matters. Sanitarians and physicians concerned with tuberculosis, industrial hygiene and workmen's compensation will find this book well worth while.

JAMES A. TOBEY

Safeguarding Mental Health—By R. C. McCarthy. *Milwaukee: Bruce Publishing Co., 1937.* 297 pp. Price, \$2.50.

Parents, teachers, and others who are concerned with the training of children will find this popularly written book worth while. Dr. McCarthy, an eminent churchman and educator, with a scientific background makes a splendid case for his thesis that complete success in life involves first of all, the observance of one's *moral and religious obligations*. Even when these terms are broadly construed, this means the ability to adapt one's self, contentedly and happily to the various difficulties which life brings.

What is the test of social adjustment? The ability to rise above one's circumstances, in itself the proof of maturity. Now such *emotional* maturity is not achieved automatically and is not the gift of time; therefore, we must strive for it intelligently and even painfully. Children, of course, are badly handicapped in such a struggle through their parent's ignorance of the means to be employed in training them. The book is obviously written to fill this need. In a word, safeguarding mental health is a matter of training the individual to keep his mental poise, something which we cannot start too young, and alas!

most people need guidance in the matter. As products of a high speed civilization, we are a high strung, nervously irritable and neurotic people. We may not return to the simple life, and life itself becomes more hasty, impetuous, and unhealthy. Therefore, since we cannot change these conditions, we *can* change our attitude toward them, which of course will involve different requirements with different people.

N. M. GRIER

Babies Are Human Beings—*By C. Anderson Aldrich, M.D., and Mary M. Aldrich. New York: Macmillan, 1938. 128 pp. Price, \$1.75.*

This is the kind of a book that many of us for some time have been hoping would appear. It is unique both in its manner of approach to a perennial subject and the interweaving of scientific facts with subtle suggestions as to how they may be applied to the growth and development of children.

The charm with which it is written grips the attention from the first page and carries one along as more complex material is introduced. It presents the baby as a dynamic individual in which no artificial lines can be drawn between the physical, mental, and emotional development. The authors insist that "in babyhood the developmental plan requires support by parents at every step," hence a book of this kind to act as a guide to parents and not as a textbook. Parents are encouraged to study the normal growth of their children so as to adopt methods of education which synchronize with stages of development. "The idea that learning is related to growth has always been appreciated by the progressive educators who have had the courage to say that the time to teach any subject to a child is when he shows that he is mature enough to learn it."

Physicians and nurses as well as parents would do well to read this

book. The publishers have exhibited their usual good taste in setting this book up in excellent form with attractive covers, readable type, and well chosen illustrations.

RICHARD A. BOLT

Research Memorandum on Migration Differentials —*By Dorothy Swaine Thomas. Social Science Research Council, Bulletin No. 43. New York, 1938. 423 pp. Price, \$2.00.*

This memorandum is a report of the Committee on Migration Differentials of the Social Science Research Council. The report attempts to meet a need for examination of the existing body of information on the differential characteristics of migrating and non-migrating groups. It is hoped that such information may serve as a foundation for further research on migration differentials.

The Memorandum is organized into eight sections each dealing with one differential. The following subjects are treated: age, sex, family status, physical health, mental health, intelligence, occupation, motivation and assimilation. Only the most significant and methodologically sound studies are fully treated in the body of the study. Others are analyzed briefly in the appendix. Extensive and annotated bibliographies are also included in the appendix.

Of particular interest to students of public health are the sections on physical and mental health differentials. The findings included in the studies analyzed seem to lead to the inference that internal migrations exercise a selective influence from the point of view of health, the migrants appearing on the whole a somewhat healthier group than non-migrants. As to mental health no definite conclusions can be drawn until we get sounder definitions of mental health and comparable methods of measuring it.

The principal value of the study lies

in the critique of method and technics for attacking the problem of migration differentials.

C. T. PIHLBLAD

Health Guides and Guards—*By Francis P. Wall and Louis D. Zeidberg, M.D. (rev. ed.). New York: Prentice-Hall, 1938. 380 pp. Price, \$1.40.*

Except for the fact that a considerable portion of the early part of the text is devoted to a description of the genital system, and to the discussion of venereal diseases, this is much like the usual text for the secondary school level. Nearly one-third of the pages are devoted to community hygiene, discussing the causes of disease, the means by which they are spread, and such factors as disinfection, water supply, milk and food protection, and sewage and refuse disposal.

At the end are some 25 pages of questions of the true-false and of the essay type on the material in the text.

One finishes the text with the feeling that too much attention is given to structures and diseases, and too little to hygiene and measures for improved healthful living.

CHARLES H. KEENE

Research Memorandum on Population Redistribution Within the United States—*By Rupert B. Vance. New York: Social Science Research Council, Bulletin No. 42, 1938. 134 pp. Price, \$1.00.*

Internal migrations and the redistribution of population in the United States are creating a whole series of new problems in the field of public health. The health needs of a community obviously are conditioned by the composition and characteristics of the population. The ability to develop and support a public health program also depends on the proportion of the population in the gainfully employable ages and upon the relation between the size of the population, the natural re-

sources, and the cultural and intellectual level attained. The rapid movements of population within the United States are rapidly changing all these conditions, hence the subject is one which deserves the close attention of all students of the public health.

The *Bulletin* reviewed here is one of a series of memoranda sponsored by the Social Science Research Council on the subject of population redistribution. It attempts to continue the work done by Dr. Carter Goodrich and others in their monograph: *Migration and Economic Opportunity*. According to the author the purpose is to "explore the redistribution of population within the United States as an area of research" by presenting the "(1) accepted interpretations in the field; (2) the materials on which these interpretations are based; (3) the gaps in the data; (4) the next lines of feasible research."

In the introductory chapter the writer explains the concept of "Population Redistribution" and methods of attacking the problem, together with some general concepts relating it to the field in which it falls. He feels that the problem may best be attacked on 5 major fronts: (1) contrasting areas of economic opportunities, (2) differential population increase, (3) differential changes in employment capacity, (4) movement of employment opportunities, and (5) internal migration and labor mobility.

In the 4 main chapters of the monograph the main conclusions to be drawn from some of the better known researches in these fields are stated and the lines along which further research seems profitable are indicated. The principal conclusions to be drawn from a review of the literature are stated in terms of some 20 or more propositions and corollaries and the lines for future research indicated in the framework of a series of queries which are to be answered by suggested research projects.

Most of the "propositions" consist of rather well recognized generalizations familiar to students of this field, as for example: "Agriculture faces a long time trend of diminishing employment capacity because increasing output per worker has met no appreciable domestic increase in per capita consumption of agricultural products and a declining export demand." Whether there is anything to be gained by stating such descriptive generalizations as fundamental "propositions" seems doubtful. The study, however, has distinct value in indicating that much more research needs to be done, and many more facts known, before we shall be in a position to develop adequate policies for control of internal migration and population distribution.

The author has performed a distinct service in indicating the lines along which such research might proceed, although the practicability of some of the projects might be questioned.

C. T. PIHLBLAD

A Textbook of Medical Bacteriology—By *David L. Belding, M.D., and Alice T. Marston, Ph.D., in collaboration with others.* New York: Appleton-Century, 1938. 592 pp. Price, \$5.00.

According to the preface, this book is intended to present a concise yet comprehensive text on bacteriology intermediate between the reference books and those which are too elementary for medical students. It is primarily a teaching text devised for medical students though it is hoped that it will be useful to practising physicians as well. The great mass of references has been omitted, and on controversial subjects only one point of view has been presented.

The relation of bacteria to public health and preventive medicine is emphasized. Immunity is presented as a distinct entity, though specific applica-

tions are considered in connection with each of the various disease producing agents. A relatively greater amount of space than usual has been devoted to the fungi and to the ultramicroscopic viruses.

On the whole, the authors have attained fairly well their objective and have produced a readable textbook. In many respects, however, they have omitted too much. For example, no staining method for Negri bodies has been given. There is a very misleading and dangerous statement to the effect that Semple's method "is extremely efficient both for treatment and prophylaxis, the fatality in treated human cases being below 1 per cent." This certainly is a recommendation of Semple's vaccine for treatment of the disease, whatever the authors may have intended it to be. As a fact, human cases of rabies die practically invariably, never mind what treatment is used, and Semple's method has never been recommended except as a preventive. The statement concerning prophylaxis in dogs by a single injection of phenolized virus annually is deficient. It has not been uniformly successful.

Some other errors are detected. On page 520, we are told that a standard milk ordinance was framed in 1926 by the "United States Public Health Association." There is no such organization and the authors doubtless refer to the Standard Ordinance of the United States Public Health Service.

In the text there are certain arrangements which are not in sequence. For example, the work of Reed in 1898, which proved the transmission of yellow fever by mosquitoes is given ahead of the discovery by Ross concerning avian malaria and his proof that the *Anopheles* mosquito was the carrier of human malaria. Smith and Kilborne were unquestionably the first to show the carrying of a disease by an insect, but the discovery of Ross was a good

deal closer to Reed's work both in time and in character than the fundamental work of Smith and Kilborne.

The index is defective. Yellow fever is not listed, though two pages are given to it. We believe also that a greater number of stains should be given.

The authors seem to have a fondness for terms which are unusual. Diphtheric, which is allowable, is used throughout the book instead of diphtheritic. Proteic seems to be the adjectival form of protein. The virus diseases are described as "viral." We have been unable to find any justification for this adjectival form. Seven pages are given to a glossary, which gives some uncommon definitions. Medical students should be taught the use of a medical dictionary and there seems to be no good reason for the glossary in a book intended for their use, and certainly any physician who can understand the text should know the terms used.

The book is generally well and interestingly written, though the student will need a good deal of supplementary information to be a finished product.

MAZYCK P. RAVENEL

The Hospital Survey for New York. *Report presented to the Survey Committee by its Study Committee.* Vol. III. *New York: United Hospital Fund,* 1938. 539 pp. Price, \$2.00.

This is Volume III published in connection with a most extensive survey carried on of the agencies which concern themselves with the varied forms of the care of the sick in Metropolitan New York.

Of the total investment in this area of almost three-quarters of a billion in hospitals of various types, nursing agencies, etc., almost \$650,000,000 represents the investment of hospitals alone. This is approximately 20 per cent of the total investment in hospitals in the whole of the United States. Al-

most \$110,000,000 are expended in greater New York annually for the maintenance of these institutions and activities; indeed, a staggering sum, the expenditure of which justifies most intensive study and analysis.

Twelve chapters in this book are devoted to a discussion of the problems confronting these hospitals, facilities for acute, chronic, and convalescent care, out-patient departments, nursing services, costs, the present methods for financing income, etc. A particularly intriguing chapter is devoted to certain prophesies as to needs in this field within the next 22 years. Estimates are based on an increase in population of approximately 7,000,000 by 1960; over \$500,000,000 for hospitals alone in Metropolitan New York.

In addition to this estimated expenditure, it is claimed that over \$50,000,000 more will be needed for reasonable facilities for the care of the chronic ill, and about \$17,000,000 for convalescent care, making for a total estimate as to future needs of over \$600,000,000.

Certainly this anticipated knowledge must make for more intelligent planning, commensurate with existing financial resources, rather than the haphazard methods which have been applied in many communities in connection with hospital development.

As an aid to those who may be planning the erection and maintenance of hospitals, as well as a volume which devotes space to cost analysis, this book should prove of great interest to hospital superintendents, to members of boards of trustees, as well as to generous givers who have made the voluntary hospital structure possible in the past.

CHARLES F. WILINSKY

Internships and Residencies—A Report by the New York Committee on the Study of Hospital Internships and Residencies. *New York: Commonwealth Fund,* 1938. 492 pp. Price, \$2.50.

In 1934, under the leadership of Dr. John Wyckoff, the five medical schools of New York City organized a committee to study the hospital internships and residencies that were available in the environs of New York. Since the internship is now generally recognized as an integral and essential part of medical education, the medical colleges believed that they should determine if the various internships that were immediately available to their graduates offered suitable and pertinent instruction which would give proper preparation for medical practice. It was anticipated that the results of this study would aid in improvement of the quality of training in the intern-

ship and hospital residence programs of the various institutions. This report is a summary of the 3 years' work.

The scope of this study is indicated by the fact that nearly 1,800 internships and residencies approved by the American Medical Association are available in the 67 hospitals that were included in this study.

The report is of value to the medical student who is planning for his internship. It is of special interest to hospital authorities who desire to improve their internships so that the training becomes of real value to their interns. Medical educators will also read this report with interest and satisfaction.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Defects We Find and Forget—
A good, honest, soul-searching consideration of school medical inspection services, which we have assumed with such complacency, is producing results in better school child health. Under the anonymous author's scrutiny a few pet assumptions about adult health examinations wither too.

ANON. School Medical Inspection or the Periodic Health Examination. Health Officer. 3, 5-6:109 (Sept.-Oct.), 1938.

Are Mental Diseases Increasing?
—Alarm-viewers will be disappointed to learn from this excellent article that data from Massachusetts, New York, and Illinois (three states that have had for some time the most nearly satisfactory institutional facilities) do not support their frequently voiced assumption that mental disorders are increasing rapidly. The apparent increase may be due to increasing life expectancy, larger proportion of old people in the population, better facilities, and more general appreciation of the value of treatment. This much is clear, the burden of caring for mental illness will increase, even if the incidence does not.

DORN, H. F. The Incidence and Future Expectancy of Mental Disease. Pub. Health Rep. 53, 45:1991 (Nov. 11), 1938.

Another Source of Encephalitis
—Equine encephalitis is transmissible to humans. In September, 1937, 6 cases were reported in Minnesota. In 1938, 8 fatal cases among youngsters in Massachusetts were studied.

EKLUND, C. M., and BLUMSTEIN, A. The Relation of Human Encephalitis to Encephalitis in Horses (and) WESSELHOEFT, C., *et al.* Human Encephalitis. J.A.M.A. 111, 19: 1734 (Nov. 5), 1938.

Pneumonia Prophylaxis—During the winter of 1936-1937, some of the men in CCC camps in New England and California were treated with Felton's pneumococcus antigen. In New England the pneumonia incidence rate was reduced nearly half and in California to one-eighth. Although the demonstration leaves some questions about length of immunity, etc., unanswered, it does suggest that a pneumonia vaccine will prove a useful prophylactic.

EKWURZEL, G. M., *et al.* Studies on Immunizing Substances in Pneumococci. Pub. Health Rep. 53, 42:1855 (Oct. 21), 1938.

Epidemiology and the Pneumococcus—Here is evidence that the type I pneumococcus is highly infectious, manifesting itself as pneumonia, suppurative ears, or just colds. Incidence of the carrier condition is high among contacts, healthy carriers being confined to adults. There is much more to be learned from this study.

GILMAN, B. B., and ANDERSON, G. W. A Community Outbreak of Type I Pneumococcus Infection. Am. J. Hyg. 28, 3:345 (Nov.), 1938.

Re Medical Economics —Sanitarians will have an academic interest, at least, in this apparently objective account of the attempt to provide prepaid medical services among certain government employees in Washington, D. C.

HARD, W. Medicine and Monopoly. Survey Graphic. 27, 12:581 (Dec.), 1938.

Studying Causes of Maternal Deaths—Maternal death rates in Massachusetts have declined from a recent peak of 6.8 per thousand in 1929

to 4.1 in 1937. The study of deaths during and since 1937 reveals, as usual, that sepsis is most to be feared. What can be done to improve the situation is profitably discussed.

HEFFERNAN, R. J. The Maternal Mortality Study in Massachusetts for 1937. *New Eng. J. Med.* 219, 22:864 (Dec. 1), 1938.

Through Neighboring Doorways

—By the use of the Municipal Doctor system, joint medical and health services have been made available to western Canadian communities for nearly two decades. Other forms of providing public medical services have been under trial for some time. It is possible that this Canadian experience will be of some value to us, if and when we begin experiments in this field.

JACKSON, F. W. Recent Extension and Future of Medical and Public Health Services (Canada). *Pub. Health.* 3, 5-6, 132 (Sept.-Oct.), 1938.

Which Diphtheria Prophylactic? Guinea pigs show superiority of alum-precipitated toxoid over unmodified toxoid. If more than one dose of antigen is to be used, the first should be alum-precipitated; the second either the same or plain.

JONES, F. G. Experiments in the Guinea Pig Comparing the Immunizing Value of Unmodified Diphtheria Toxoid and Alum-Precipitated Toxoid. *Am. J. Hyg.* 28, 3:359 (Nov.), 1938.

For All To Ponder Over—Among Massachusetts patients with chronic disease, one in four had not sought medical care. Most failed to get this help because of lack of understanding of the need rather than inability to pay. Cancer patients continue to delay in seeking medical care, and patients with other chronic conditions are in need of persuasive education.

LOMBARD, H. L. Education A Major Need in Adequate Medical Care. *J.A.M.A.* 111, 19:1747 (Nov. 5), 1938.

And May Their Tribe Increase—These tables showing the marked improvement in the employment of public health nurses make good reading indeed. Statistics about who employs the nineteen-odd thousand nurses are also of interest to all of us.

REID, M. 1938 Census of Public Health Nurses. *Pub. Health Nurs.* 30, 11:632 (Nov.), 1938.

Nutrition Versus Caries—Milk with vitamin D added to an otherwise unbalanced institutional diet did not prevent the extension of dental caries, though the condition of teeth of children fed the milk supplement was slightly better than the controls. The moral is that other nutritional factors are involved in the prevention of caries.

ROBERTS, L. J., *et al.* Effect of a Milk Supplement on the Physical Status of Institutional Children. *Am. J. Dis. Child.* 56, 4:805 (Oct.), 1938.

Nutrition and Tomorrow's Hygiene—Lesions of the nervous system common in beriberi, pellagra, and in polyneuritis associated with many other conditions are traceable to vitamin B deficiency. In the future many other neurologic and perhaps psychiatric complexes will be found due to the same cause. This paper is another pointer to the part nutrition will play in the hygiene of tomorrow.

SHATTUCK, G. C. Nutritional Deficiency and the Nervous System. *J.A.M.A.* 111, 19:1728 (Nov. 5), 1938.

Guinea Pigs Confirm Grandma's Unshaken Belief—Experiments are reported which suggest that morbid body changes following chilling are due to constriction of peripheral blood vessels, lowered leucocyte response, and impairment of protective capabilities of tissue cells. These changes predispose to infections of upper respiratory tract.

TAYLOR, H. M., and DYRENFORTH, L. Y. Chilling of the Body Surfaces. *J.A.M.A.* 111, 19:1744 (Nov. 5), 1938.

ASSOCIATION NEWS

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

- Theodore J. Bauer, M.D., 112 Federal Bldg., San Francisco, Calif., Passed Assistant Surgeon, U. S. Public Health Service
 Fred P. Long, M.D., Box 443, North Platte, Nebr., Director, Demonstration District Health Unit
 Thomas Morcom, M.D., Nome, Alaska, Assistant Commissioner of Health, Territory of Alaska
 William P. Rice, M.D., C.P.H., 1818 Delaney St., Orlando, Fla., Director, Orange County Health Unit
 Dr. Gustavo A. Roviroso, Calle de Zamora 174, Mexico, D. F., Mex., Jefe de la Oficina Central de Higiene Rural, Dept. of Health
 Pearl A. Toivonen, M.D., Ontonagon, Mich., County Health Officer
 Donald H. Williams, M.D., 2700 Laurel St., Vancouver, B. C., Canada, Director, Venereal Disease Control, Provincial Board of Health

Laboratory Section

- Kathleen H. Clark, 2830 Bancroft Way, Berkeley, Calif., Student
 Claude E. Dolman, Ph.D., D.P.H., 763 Hornby St., Vancouver, B. C., Canada, Director, Division of Laboratories, Provincial Dept. of Health
 Daniel M. Eisler, 401 N. Fourth Ave., Ann Arbor, Mich., Student
 Harry B. Harding, 2526 College Ave., Berkeley, Calif., Associate in Public Health, Dept. of Hygiene, Univ. of Calif.
 Margaret R. Harrison, U. S. Marine Hospital, Staten Island, N. Y., Associate Chemist, U. S. Public Health Service
 Thomas F. Judefind, M.D., College of Medical Evangelists, Loma Linda, Calif., Instructor in Bacteriology
 Richard H. Knapper, 711 Forbes St., Pittsburgh, Pa., Research in Apparatus for Public Health and Hospital Laboratories, Fisher Scientific Co.
 Mercedes Luxen, 283 Alvarado St., Chula Vista, Calif., Student

- John F. Mahoney, M.D., U. S. Marine Hospital, Stapleton, Staten Island, N. Y., Director, Venereal Disease Research Laboratory, U. S. Public Health Service
 Fred Nussberger, 44-14 Rd., Broad Channel, N. Y., Chemical Laboratory Assistant, Dept. of Health
 Anna I. van Saun, Board of Health, Paterson, N. J., Director of Laboratory, Board of Health
 Herbert G. Weitzman, 1934 Haste St., Berkeley, Calif., Student
 Jack C. Wyatt, City Hall, Amarillo, Tex., Chemist in charge of sanitation, Amarillo-Potter County Health Unit

Vital Statistics Section

- Frank M. Beresford, M.D., 4601 Market St., Philadelphia, Pa., Medical Director, Provident Mutual Life Insurance Co.
 John J. Sullivan, Jr., 520 E. Jefferson, Ann Arbor, Mich., Trainee for Nevada State Board of Health

Public Health Engineering Section

- Tim Green, Kingfisher County Public Health Dept., Kingfisher, Okla., Sanitarian
 Alexander T. Kogut, 23 Gould St., Wakefield, R. I., Sanitary Investigator and Adviser, State Dept. of Public Health
 Daniel E. Lynch, Jr., 810 Ocean Ave., Brooklyn, N. Y., Chemist, Bureau of Sewage Disposal, City Dept. of Public Works
 Willard S. Sitler, Allegan County Health Dept., Allegan, Mich., Student Sanitarian

Industrial Hygiene Section

- Ralph W. Ryan, P. O. Box 101, Charleston, W. Va., Chemist and X-ray Technician, State Workmen's Compensation Commission

Food and Nutrition Section

- Samuel S. Altshuler, M.D., 313 David Whitney Bldg., Detroit, Mich., Student

Child Hygiene Section

- Michael Antel, M.D., Harvard School of Public Health, Boston, Mass., Fellowship on leave from New York City Dept. of Health

Helen Cannon, 3136 York St., Denver, Colo., Medical Social Worker, Colorado Division of Crippled Children.

Cleo Chastain, M.D., 670 Georgia Ave., Chattanooga, Tenn., School Physician, City Health Dept.

Ernest Couture, M.D., Dept. of Pensions and National Health, Ottawa, Ont., Canada, Director, Division of Child and Maternal Hygiene

Irene P. Koenig, M.D., 1986 Crotona Ave., New York, N. Y., Physician

Martha Leslie, 519 Smithfield St., Pittsburgh, Pa., Executive Secretary, Child Health Div., General Health Council

Louis A. Simon, D.D.S., 1 W. 85 St., New York, N. Y., Dentist, Dept. of Health

Public Health Education Section

Nellie A. Blake, 911 W. Washtenaw St., Lansing, Mich., Health Education Director, City Health Dept.

William A. Doppler, Ph.D., 57 Olcott Ave., Bernardsville, N. J., Field Adviser, Health Education Service, National Tuberculosis Assn.

Ruth R. Frankel, 510 Ocean Ave., Brooklyn, N. Y., Teacher, Dept. of Hygiene, Brooklyn College

Jacob S. Hoffman, M.D., 408 Argyle Bldg., Kansas City, Mo., Physician

Michael Kley, 1 Madison Ave., New York, N. Y., Field Representative, Welfare Div., Metropolitan Life Ins. Co.

Edward G. Trigg, V.M.D., 144 Hill St., Ann Arbor, Mich., Student on leave (Associate Professor of Hygiene and Bacteriology, Virginia State College)

Public Health Nursing Section

Elizabeth Albrecht, 971 First Ave., New York, N. Y., Assistant Supervisor, Henry Street Visiting Nurse Service

Nadyne V. Anderson, R.N., 1016 S. Moniteau, Sedalia, Mo., Orthopedic Field Nurse, State Crippled Children's Service

Hedwig Cohen, 615 W. 172 St., New York, N. Y., Supervisor of Nurses, Henry Street Visiting Nurse Service

Christine Cole, R.N., Box 185, Thomaston, Ga., Upson County Public Health Nurse

Mary Davis, 728 Lake Ave., Manchester, N. H., Director, Public Health Nursing Division, State Dept. of Health

Dorothy A. Harding, R.N., 1607 S. State St., Ann Arbor, Mich., Student

Edith M. John, 78-12-35 Ave., Jackson Heights, L. I., N. Y., Assistant Supervisor, Henry Street Visiting Nurse Service

Geraldine J. Miller, R.N., 300 S. Broadway, Wichita, Kans., Nurse, Sedgwick County Health Dept.

Helene Moos, R.N., 315 W. 91 St., New York, N. Y., Nurse, Dept. of Health

Mary C. Wolking, 3765 Vermont St., San Diego, Calif., Supervising Public Health Nurse, San Diego County Health Dept.

Epidemiology Section

Emanuel Sigoloff, M.D., 642 Missouri Bldg., St. Louis, Mo., Charge of Pneumonia Control Program, St. Louis Health Division

Unaffiliated

Leonard J. Duckworth, 4544 Tulip Ave., Oakland, Calif., Student

Oscar A. Dudley, M.D., 476 Main St., Worcester, Mass., District State Health Officer

Margaret K. Fiscalini, Route 3, Box 657, Modesto, Calif., Student

John M. Geary, 501 W. 121 St., New York, N. Y., Student

Hugo V. Hullerman, M.D., 332 E. Jefferson St., Ann Arbor, Mich., Trainee

Saul Karch, 2711 Pasadena, Detroit, Mich., Student

Frederick A. Musacchio, M.D., 2101 Devonshire, Ann Arbor, Mich., Student

Walter J. Pelton, D.D.S., 705 Oakland Ave., Ann Arbor, Mich., Passed Assistant Dental Surgeon, U. S. Public Health Service—Student at present

DECEASED MEMBERS

R. B. Durfee, M.D., Bisbee, Ariz., Elected Member 1919, Fellow 1934

I. Malinde Havey, R.N., Washington, D. C., Elected Member 1922, Fellow 1932

Frank W. Laidlaw, M.D., Middletown, N. Y., Elected Member 1927, Fellow 1930

John M. J. Raunick, M.D., Harrisburg, Pa., Elected Member 1915, Fellow 1922

Henry C. Becker, M.D.V., Chicago, Ill., Elected Member 1927

Wesley M. Graff, New York, N. Y., Elected Member 1936

EMPLOYMENT SERVICE

The Employment Service will register persons qualified in the public health field without charge.

Replies to these advertisements, indicating clearly the key number on the envelope, should be addressed to the American Public Health Association, 50 W. 50 Street, New York, N. Y.

POSITIONS WANTED

HEALTH OFFICERS

Well qualified physician, with C.P.H. from Johns Hopkins; experienced as school physician and in college teaching, will consider city or county administrative position or teaching and student health service. A383

Physician, M.D., Class A medical school; M.S.P.H., University of Michigan, 1937; now serving as district state health officer, seeks full-time administrative position in city or county. A367

Physician, M.D., Class A medical school; M.P.H., Harvard School of Public Health; extensive experience in pediatrics and school medical services; also background of county health administration and teaching in medical school, will consider expanded opportunity in teaching or research. A302

Physician, M.D., C.P.H., 2 years' experience as district health officer; prefers to do venereal disease control work or epidemiology. A345

Physician, with M.P.H. from Harvard, experienced as epidemiologist and in county health administration, also in communicable diseases at state level, seeks responsible position. A392

Physician, M.D., University of Cincinnati; with postgraduate training in venereal disease control, Johns Hopkins; now employed, is available as venereal disease control officer. A363

HEALTH EDUCATION

Young woman, M.S.P.H., University of Michigan, experienced in laboratory research

and health education, is available for research or investigative work. H303

Dentist, with wide training and experience in educational lines, wishes responsible position in health education. H393

LABORATORY

Capable research worker; Ph.D., trained at University of Southern California and Pasteur Institute, seeks position directing laboratory, in research work or field investigation. Has taught bacteriology, directed state hygiene laboratory and hospital laboratories. L315

Woman bacteriologist; B.A., Chemistry, 1933; 5 years' experience in experimental and practical therapeutics including animal work; desires position in public health field. L394

Laboratory technician, who has had experience in a variety of laboratory and inspection positions, seeks an appointment in the Midwest or Southwest. Good references. L395

MISCELLANEOUS

Industrial hygiene engineer, S.M. in Sanitary Engineering (Industrial Hygiene) from Harvard Graduate School of Engineering; field experience; desires position with public health department or private health agency. M391

Experienced teacher in bacteriology and public health; Ph.D., Cornell; now professor in Grade A medical school, will consider teaching, executive or administrative position. M327

NEWS FROM THE FIELD

SOUTHERN BRANCH OFFICERS

AT its Seventh Annual Meeting, held in Oklahoma City, Okla., November 15-16, 1938, the Southern Branch of the American Public Health Association elected the following officers to serve for the forthcoming year:

President—J. N. Baker, M.D., Montgomery, Ala.

First Vice-President—W. B. Grayson, M.D., Little Rock, Ark.

Second Vice-President—V. M. Ehlers, C.E., Austin, Tex.

Third Vice-President—Donna Pearce, R.N., Washington, D. C.

Secretary-Treasurer—P. E. Blackerby, M.D., Louisville, Ky.

25TH ANNIVERSARY OF WALLACE & TIERNAN

WALLACE & Tiernan Co., Inc., Newark, N. J., celebrated the 25th Anniversary of its incorporation—November 13, 1913—with a series of Silver Jubilee celebrations.

November 11 was selected as the nearest working day to the actual Anniversary date, Sunday, November 13. Beginning the formal ceremonies at 11 A.M., two minutes of silence commemorating Armistice Day, was followed by an interesting program. Mr. M. F. Tiernan, President of the Company, reviewed various highlights in the growth of the organization from the date of its incorporation. He traced the growth of the organization through its 25 years of existence to today with its thousand or more employees—with its extensive headquarters office and factory buildings occupying over 6 acres at Belleville, N. J., and with additional factories in Canada and England and 42 sales and service headquarters, together with representatives in over 57 foreign countries.

William J. Orchard, General Sales Manager, said, "... every product or process marketed by the company is a direct benefit to the welfare of mankind touching on the preservation of health or life itself."

Mr. Tiernan touched upon the activities of the organization in the manufacture of chlorine control apparatus, the development of processes for maturing and bleaching flour, treatment of various industrial process waters, the chlorination of condenser water, production of lighted aids to navigation for the U. S. Lighthouse Service, development of nautical radio beacon control apparatus, development of a process for the prevention of decay in fruit and vegetables, and acquisition by Novadel-Agene Corporation (an affiliate) of the Kooler-KeG Beer Dispensing System. Mr. Tiernan introduced Judge Charles E. McMahon of New York City, who drew the original incorporation papers of Wallace & Tiernan Company, and who spoke on "W & T 25 Years Ago—and Since."

NEW JERSEY HEALTH AND SANITARY ASSOCIATION

THE 64th Annual Meeting of the New Jersey Health and Sanitary Association, was held at Asbury Park, N. J., November 18-19, 1938, in cooperation with the Conference of Health Officers—New York Metropolitan Area, New Jersey Health Officers Association, American Social Hygiene Association, and the New Jersey Anti-Syphilis Committee. Approximately 900 delegates attended.

The new officers elected were:

President, Joseph R. Morrow, M.D., Ridgewood

1st Vice-President, L. D. Bristol, M.D., Montclair

2nd Vice-President, L. VanD. Chandler, Hackensack

3rd Vice-President, Joseph E. Raycroft, M.D., Princeton

Secretary, Edward Guion, M.D., Northfield

Treasurer, Budd H. Obert, Asbury Park

FLORIDA PUBLIC HEALTH ASSOCIATION

THE Tenth Annual Meeting of the Florida Public Health Association was held at Hollywood, Fla., November 28-30, 1938. The attendance was the largest in the history of the association and the papers were of high quality and interest.

Special attention was centered on three diseases which are of particular concern to this state, namely, yellow fever, malaria, and hookworm infestation. One paper of great interest had to do with sanitary precautions on International Airways. This was especially timely since Miami handles more international airplane passengers than any airport in the United States.

The following officers were elected to serve until the next annual meeting to be held in Jacksonville late in 1939, the exact time having not yet been determined.

President—S. D. Macready, West Palm Beach

First Vice-President—A. P. Black, Ph.D., Gainesville

Second Vice-President—Elizabeth Reed, Marianna

Secretary-Treasurer—Edward M. L'Engle, M.D., Jacksonville

CONFERENCE OF MUNICIPAL PUBLIC HEALTH ENGINEERS

A NEW organization known as "The Conference of Municipal Public Health Engineers" was formed on Wednesday, October 26, during the 1938 Sessions of the American Public Health Association, with the following officers:

Chairman—Joel I. Connolly, Chicago, Ill.

Vice-Chairman—Aimé Cousineau, Montreal.

Secretary-Treasurer—Alfred H. Fletcher, Memphis, Tenn.

Executive Committee:

James L. Barron, Nassau County, N. Y.

Arthur E. Gorman, Chicago, Ill.

Henry C. Lane, Minneapolis, Minn.

F. Gardner Legg, Detroit, Mich.

Sol Pincus, New York, N. Y.

The first meeting will be held on Monday, one day immediately preceding the 1939 Convention of the American Public Health Association. This new organization will provide a medium for an exchange of ideas relating to the problems of the municipal public health engineer, to the end that the various activities, studies, measures, methods and administrative procedures for carrying on effective engineering health programs and that coöperation to the mutual benefit of the Conference of State Sanitary Engineers, and the Engineering Section of the American Public Health Association, may be encouraged.

Sanitary and public health engineers in health, water, industrial, and similar related departments of municipalities and urban areas are eligible for membership.

DR. VAUGHAN 25 YEARS DETROIT HEALTH COMMISSIONER

ON January 1, Henry F. Vaughan, D.P.H., will have completed 25 years with the Detroit, Mich., Department of Health.

He will be honored by a dinner given by the staff, to which many people prominent in public health fields will be invited.

PERSONALS

Central States

PHILIP E. M. BOURLAND, M.D., M.S.P.H.,† of Lansing, Mich., recently with the Michigan State Board of Health, has been appointed Director of the Dickinson County Health Unit, succeeding CLIFTON E.

† Member A.P.H.A.

MERRITT, M.D.,† of Bay City, who accepted a similar position in Bay County.

CLIFTON C. CORKILL, M.D.,† of Ontonagon, Mich., Director of the Ontonagon-Baraga Counties Health Unit, has been appointed in charge of the Menominee County Health Department. He succeeds LAWRENCE A. BERG, M.D.,† of Detroit, who is on a year's leave of absence to take a graduate course at the University of Michigan Medical School, Ann Arbor, Mich.

CLAUDE MILTON EBERHART, M.D.,† of Highland, Ill., has been appointed Director of the new health unit including Bond, Clinton, Madison, and St. Clair Counties.

DR. MAURICE GORE, of Aurora, Ill., has been appointed Medical Officer in Charge of the new Health District embracing the Counties of DeKalb, Grundy, Kane, Kendall, and LaSalle.

DR. REUBEN J. HARRINGTON, for 14 years Health Officer of Muskegon, Mich., has been appointed in charge of the unit in Muskegon County, succeeding RICHARD SEARS, M.D.,† of the Michigan State Department of Health.

DR. WILLIAM D. HART has been appointed Director of District Health Unit No. 4, Rising Sun, Ind., succeeding GEORGE M. BROTHER, M.D.,† who is taking a year's study at Johns Hopkins University School of Hygiene and Public Health, Baltimore, Md.

RUSSELL E. PLEUNE, M.D.,† of Lansing, Mich., who was scheduled to take over the post in Dickinson County, is now Director of the Houghton-Keweenaw Health Unit, succeeding FORREST J. AUSTIN, M.D.,† of Houghton.

GUY R. POST, M.D.,† has resigned as Director of the Tri-County Health Unit, serving Newaygo, Lake, and

Oceana Counties, Mich., effective September 15.

ALBERT J. RANDALL, M.D.,† Assistant Director of Health in Kenosha, Wis., has been appointed Director, to succeed GUSTAVE WINDESHEIM,* who retired October 15.

ISAAC D. RAWLINGS, M.D.,* for many years Chief of the Bureau of Communicable Diseases of the Chicago, Ill., Board of Health, has retired.

DR. JOHN F. SHRONTs has been appointed District Health Officer of the new district health department established in Woodstock, Ill., to serve the Counties of Boone, Lake, McHenry, and Winnebago.

MRS. LUCILLE SMITH, Director of Medical Service for the Chicago Relief Administration, resigned October 6 to accept a position with the Social Security Board in Washington, D. C.

DR. LEONARD S. STEADMAN, of Junction City, Kans., has been appointed Health Officer of Geary County, to succeed DR. ROBERT J. LANNING, who recently retired to enter private practice.

DR. WALTER P. STOLTENBERG, of Kinsley, Kans., has been appointed Health Officer of Edwards County.

DR. JOHN S. WOOLERY, of Bedford, Ind., has been appointed Health Officer of Lawrence County, filling the unexpired term of the late DR. WESLEY H. MCKNIGHT.

Eastern States

JOHN H. R. BARRY, M.D.,† of Long Island City, N. Y., for 30 years Assistant Sanitary Superintendent for the Borough of Queens, has retired from the city service.

DR. DAVID BAST, of New York, N. Y., has been named Assistant Director for Oral Hygiene, Division of Maternity, Infancy and Child Hygiene,

* Fellow A.P.H.A.
† Member A.P.H.A.

New York State Department of Health.

DR. EDWARD J. BROPHY is Health Officer of Norwich, Conn., filling the unexpired term of the late DR. HARRISON GRAY.

DR. BYRON H. FARRALL, of Boscawen, N. H., Director of the Division of Maternal and Child Health and Crippled Children Services of the New Hampshire State Board of Health, has resigned. He is to be succeeded by DR. MARY ATCHISON, formerly of Dubuque, Ia.

DR. ARCHIBALD M. GAULOCHER, of Wingdale, N. Y., is Health Officer of Kent, Conn.

DR. MALCOLM GOODRIDGE, Professor of Clinical Medicine at the Cornell University Medical School, New York, N. Y., will succeed DR. JAMES ALEXANDER MILLER as President of the New York Academy of Medicine.

ALMA MCCLINTOCK, R.N.,† recently became Supervisor of the State Health Nurses in Allegheny County, City of Pittsburgh, Pa.

DR. DONALD J. MCCRANN, of West Hartford, Conn., has succeeded DR. MAURICE B. THOMPSON as Health Officer of Bloomfield.

DR. ROBERT E. PERDUE was appointed the first full-time Health Officer of Norwalk, Conn., effective Sept. 1. Norwalk is now the 9th city in Connecticut to be on a full-time basis.

FRANK D. URSONE, M.D.,† of Norfolk, Conn., is Health Officer of Colebrook.

DR. CHARLES A. WEAVER, of Concord and Manchester, N. H., has retired after more than 20 years of service with the New Hampshire State Board of Health as Epidemiologist and Director of Venereal Disease Control. Dr. Weaver is 83 years old and graduated from the University School of Medicine in 1881. DR. JOHN S. WHEELER, of Wolfeboro, N. H., will take Dr. Weaver's place temporarily.

Southern States

DR. PAUL W. BOWDEN has been appointed Assistant Health Officer of the Arlington County, Va., Department of Health and Welfare.

HAROLD W. BROWN, M.D., Sc.D., DR.P.H.,† Chapel Hill, N. C., has been appointed Professor of Preventive Medicine and Public Health at the School of Medicine, Duke University, Durham, N. C.

DR. LYMAN T. COX, of El Paso, Tex., has been appointed Health Officer of the city and county of El Paso, succeeding JOHN W. TAPPAN, M.D.†

DR. DURWOOD L. DODD has been appointed Health Officer of Austin, Tex., succeeding DR. FRANCIS BANNER GREGG.

JOHN W. DUGGER, M.D.,† of Jackson, Miss., of the Mississippi State Department of Health, has been appointed in charge of the Marshall County Health Department, succeeding DR. VERNON B. HARRISON, of Holly Springs, who has been granted a year's leave of absence to serve as Assistant Professor of Bacteriology and Preventive Medicine at the University of Mississippi School of Medicine.

HERMAN F. EASOM, M.D.,† of Raleigh, N. C., has been appointed Chairman of the newly formed Committee on Industrial Health of the Medical Society of the State of North Carolina.

DR. ARTHUR GLECKLER, of Sherman, Tex., was recently appointed Health Officer of Grayson County, succeeding DR. BUFORD A. RUSSELL.

DR. EDWARD R. GRAY has been appointed Assistant Chief Statistician in the Division of Financial Statistics of States and Cities, of the Bureau of the Census, Department of Commerce, Washington, D. C.

* Fellow A.P.H.A.

† Member A.P.H.A.

CHARLES C. HEDGES, M.D., Health Officer of the Isle of Wight-Nansemond-Suffolk County Health Department, Va., has been appointed first Medical Assistant to K. E. MILLER, M.D.,* Director of the Medical Division of the Federal Trade Commission, Washington, D. C.

DR. ULYS JACKSON, of Harrison, Ark., has been appointed Medical Director of District No. 14 of the Arkansas State Department of Health, with headquarters in Marshall.

DONALD B. McMULLEN, D.Sc., has been appointed Assistant Professor of Bacteriology at Johns Hopkins University, Baltimore, Md.

LEWIS B. SIMS has been appointed Technical Assistant to the Chief Statistician in the Division of Financial Statistics of States and Cities, of the Bureau of the Census, Department of Commerce, Washington, D. C.

DR. EARNEST L. THOMPSON, of Hot Springs National Park, Ark., has been appointed in charge of the Garland County Health Department, succeeding the late DR. JAMES F. MERRIT.

Western States

DR. ALEXANDER B. BIGLER has been appointed City Health Officer of Chowchilla, Calif., succeeding DR. ALTON C. ATWOOD.

DR. CORNWALL C. EVERMAN is Health Officer of Larkspur, Calif., formerly served by DR. LOUIS L. ROBINSON.

DR. WALTER W. FENTON, Health Officer of San Bernardino County, Calif., will be in charge also of the public health affairs of the city of Needles, recently transferred to the county administration.

RALPH GREGG, M.D.,† of the U. S. Public Health Service, recently stationed in Tacoma, Wash., has been assigned to be Health Officer of Tacoma, succeeding the late SAMUEL M. CRESWELL, M.D.*

DR. FREDERICK W. KNIGHT has been appointed Health Officer of Corcoran, Calif., to succeed the late DR. JAMES H. VANVORHIS.

DR. MORRIS KRUTCHKOFF has been appointed Health Officer of Fernald, Calif., succeeding DR. JOSEPH M. BROWN.

DR. ELLERT E. LUNDEGAARD, of Weimar, Calif., has been appointed Health Officer of Colfax, to succeed DR. RAY C. ATKINSON.

DR. THOMAS L. MEADOR, of Portland, Ore., has been appointed in charge of the Division of Communicable Disease in the city Department of Health.

DR. HAROLD J. SHANKS is now Health Officer of Pleasanton, Calif., succeeding the late DR. WILLIAM D'ARCY CHACE.

DR. DAVID G. SMITH is Health Officer of Corte Madera, Calif., formerly served by DR. LOUIS L. ROBINSON.

DEATHS

LEROY W. HUBBARD, M.D., of Mount Vernon, N. Y., died August 31, 1938. He was connected with the New York City Department of Health from 1897 to 1914, when he joined the State Department of Health. Since 1927 he was connected with the Warm Springs Foundation, Warm Springs, Ga.

L. W. HUTCHCROFT,† Director of the Bureau of Vital Statistics, Wisconsin State Board of Health, died September 28, 1938.

School; and Lieut. Colonel, Medical Corps, U. S. Army,
Director of Laboratories, Army Medical School,
Washington, D. C.*

TWO progress reports have been published on the studies being made of typhoid vaccine in the laboratories of the Army Medical School.^{1, 2}

During the past two years we have had the opportunity to undertake experimental studies with a view to estimating the duration of the protection afforded by the vaccine. Also, a study has been made of the value of re-vaccination with a single small dose of vaccine intracutaneously injected. This paper is a progress report of these two phases of our studies of typhoid vaccine.

DURATION OF IMMUNITY

The presence of protective antibodies in the blood stream after vaccination with typhoid vaccine is one indication of immunity, and the persistence of such antibodies over a period of time may be utilized to estimate the duration of the immunity conferred by the vaccine. In conducting these studies, we have used the mouse protection test to measure the antibody content of the blood serum. The mouse protection test measures the passive immunity conferred on mice by the inoculation of blood serum of an immunized individual. This test, as we have used it in our work, has been described in a previous communication.²

Preliminary to the experimental

* Presented by Lieut. Colonel G. C. Dunham, M.C., before the Laboratory Section of the American Public Health Association at the Sixty-seventh meeting in Kansas City, Mo., October 26, 1938.

studies regarding duration of immunity in vaccinated individuals, a study was made of a group of individuals who had never been vaccinated and who presented no history of having had typhoid fever. In all tests made before vaccination a constant dose of 10,000 organisms was used against 0.1 c.c. of individual's serum, on the assumption that if 0.1 c.c. of the blood serum of an individual afforded mice no protection against 10,000 live virulent typhoid organisms, the individual, arbitrarily, could be considered non-immune. This method was used as a screening test to eliminate those who were highly immune, and to conserve mice; also, because of the difficulty of determining the end point where the protective antibody content of the serum is very low.

All such tests were controlled by injection into groups of mice of 10, 100, and 1,000 organisms without serum, to determine the minimum lethal dose of the culture being used. In this series of observations, it was found that the minimum lethal dose for the control mice was either 100 or 1,000 organisms. Consequently, where, for example, an individual's serum did not protect mice against the dose of 10,000 organisms, the number of m.l.d. against which that serum, theoretically, would afford no protection might be as low as 10 or 100, depending on the

virulence of the culture used. In Table I, the results of the tests are expressed as the number of m.l.d. of the test organism (Strain No. 63 *infra*) against which the serum protected or failed to protect mice.

A constant dose of 10,000 organisms was used in testing sera before vaccination. In some of the cases included in this study, 10,000 organisms of the culture used represented 100 m.l.d. for the control mice, while in other cases 10,000 organisms represented only 10 m.l.d. The former are placed in the first group and the latter in the second group in Table I. It is possible that the blood sera of many of the 176 persons in the first group which failed to protect mice against 100 m.l.d., would also have failed to protect against 10 m.l.d. had 1,000 instead of 10,000 test organisms been used.

Apparently, in many instances, the adult individual possesses some immunity to typhoid fever, even though he has not had typhoid fever in a diagnosable form and has never been immunized by vaccination. Our studies indicate that the protective antibody content of the blood sera of a large proportion of these individuals is relatively low, as compared with that of vaccinated persons. As shown in Table I, the blood sera of 79 per cent of the first group of 222 persons failed to protect mice against 100 m.l.d. of the test

TABLE I

Protective Antibody Content of Blood Sera of Individuals Not Vaccinated. Results Are Expressed as the Number of Minimum Lethal Doses of the Test Organism Against Which the Serum of the Individual Tested Protected, or Failed to Protect, Mice

* The test dose consisted of 10,000 organisms and represented either 10 or 100 minimum lethal doses, depending upon the virulence of culture used.

organism, and 76 per cent of the second group of 214 failed to protect against 10 m.l.d.

In this study, the blood sera of 21 per cent of the first group and 24 per cent of the second group protected mice against more than 100 m.l.d. and 10 m.l.d., respectively. It is quite probable that the group contained some individuals who had had undiagnosed typhoid fever, in which case their blood sera would have protected mice against a much higher number of m.l.d. Obviously, the use of a single fixed dose of organisms, the technic first adopted for all preliminary titrations, even though it amply sufficed to pick out the non-immunes, would give no definite information concerning immunes. In our more recent work we are expanding the dosage in such manner as will enable us to secure the end point in all preliminary titrations.

A group of 200 individuals was studied with a view to determining the protective antibody content of the blood serum shortly after immunization. In each instance, the blood was taken on the 14th day after the third inoculation of typhoid vaccine. No one of this group had received more than the one course of vaccine, and none gave a history of having had typhoid fever. The results are shown in Table II, and are expressed in multiples of the m.l.d. of the test organism against which 0.1 c.c. of the individual's serum completely protected mice.

The results of the tests, as shown in Tables II, III, and IV, are expressed in terms of complete protection afforded mice against multiples of the m.l.d. for mice of a virulent strain of the typhoid bacillus suspended in mucin (5 per cent). A strain designated in our laboratories as Strain No. 63 was used for this purpose.

It will be noted in Table II that 2 weeks after vaccination the blood sera protected mice against from a mini-

10,000	121	60.5
1,000	40	20.0
Total	200	100.0

mum of 1,000 to a maximum of 1,000,000 m.l.d. of the test organism. In 80 per cent of the observations, the sera protected against at least 10,000 m.l.d.

Three groups of individuals have been studied with regard to the duration of immunity for varying periods of time. In one group, consisting of 56 persons, the blood sera were retitrated from 12 to 17 months after the initial vaccination. In another group of 30 individuals, the blood sera were retitrated after an interval of from 24 to 29 months subsequent to initial vaccination. In all instances, the individuals comprising these two groups were immunized with vaccine made from a virulent strain (Strain No. 58) and the blood sera had been titrated 2 weeks after initial vaccination. None of those included in this study gave a history of previous vaccination or of having had typhoid fever. The results obtained are shown in Table III.

It is apparent that the number of observations in Table III are too few to permit drawing definite conclusions on a statistical basis. However, the results obtained, while subject to confirmation by additional studies, do indicate the trend in the persistence of immunity as conferred by immunization with typhoid vaccine, in so far as

TABLE III

*Protective Antibody Content of Blood Sera of 56 Persons 12 to 17 Months, and of 30 Persons 24 to 29 Months Subsequent to Vaccination with Typhoid Vaccine. Results Are Expressed in Minimum Lethal Doses of the Test Organism Against Which the Serum of the Individual Protected Mice **

Total	56	100.0	30	100.0

* Two weeks subsequent to vaccination these blood sera protected mice against from 1,000 to 1,000,000 m.l.d. of the test organism.

the mouse protection test can be used as a measure of the immunity possessed by the individual.

Twelve to 17 months after immunization the blood sera protected mice against from 100 to 10,000 m.l.d. of the test organism. Twenty-four to 29 months after vaccination the blood sera protected mice against from 1 to 10,000 m.l.d. (Table III).

During a period of 12 to 17 months subsequent to vaccination, the blood sera of 39 of the 56 individuals, or 69 per cent of the group, afforded mice complete protection against at least 1,000 m.l.d. of the test organism. Two years after vaccination the blood sera of 14 of the 30 individuals, or 46 per cent of the group, protected mice against 1,000 lethal doses of the test organism.

Despite the relatively great decrease in the protective antibody content of the blood in from 1 to 2 years subsequent to immunization, as measured by the mouse protection test, the average member of the groups observed, and the majority of the individuals involved, still have considerable immunity 1 year and 2 years after vaccination, as is indicated by the persistence of protective antibodies sufficient to pro-

test mice against a relatively large number of minimum lethal doses of the test organism.

The third group consists of 311 individuals who had been vaccinated from one to several times, and among whom the time interval since the last vaccination ranged from 1 year to more than 10 years (Table IV). No data are available relative to the protective antibody content of the blood sera 2 weeks after vaccination, as for the groups discussed above (Tables II and III).

The blood sera of the members of the group who received their last course of vaccine 12 to 24 months previously protected mice against from 1 to 10,000 m.l.d. of the test organism. The blood sera of 62 per cent of this group protected mice against at least 1,000 m.l.d. These findings are comparable to those shown in Table III.

The blood sera of the members of the group vaccinated from 24 to 36 months before they were tested also protected mice against from 1 to 10,000 m.l.d., and 35 per cent of the sera protected mice against at least 1,000 m.l.d.

Thereafter, the protective antibody content of the blood sera of individuals

TABLE IV

Protective Antibody Content of Blood Sera of Previously Immunized Individuals at Different Periods of Time Subsequent to Last Vaccination. Results are Expressed in Minimum Lethal Doses of the Test Organism Against Which the Serum of the Individual Protected Mice

last vaccinated from 4 to 5 years, 6 to 10 years, and more than 10 years prior to the time of testing decreased gradually and more slowly. While the numbers of persons involved in the 4 to 5 years, 6 to 10 years, and more than 10 years groups are relatively small, the results suggest that some degree of immunity persists for a long period of time—more than 10 years—after immunization with typhoid vaccine. It should be noted, however, that most of the members of these groups had been vaccinated two or more times.

COMMENT

Determination of the protective antibody content of the blood subsequent to immunization with typhoid vaccine, through the ability of the blood serum to confer passive immunity to mice, cannot be considered as measuring the total potential defense response of the immunized individual to typhoid fever. However, the production of immune substances and their presence in the blood, as shown by the mouse protection test, is a part of the response of

the defense mechanism of the tissues to the inoculation of typhoid vaccine, and is demonstrable evidence of immunity to infection with *E. typhosa*.

As shown in Table II, the degree of immunity present in different individuals 2 weeks after vaccination varies widely. At this time all of the blood sera tested protected mice against at least 1,000 m.l.d. of the test organism, and 80 per cent protected against at least 10,000 doses, 20 per cent against 100,000 doses, and 2 per cent against one million m.l.d. Immediate protective antibody concentration in the blood serum sufficient to protect mice against 1,000 minimum lethal doses of virulent organisms appears to represent the minimum immunity conferred by vaccination with typhoid vaccine, when given in three subcutaneous injections of 0.5 c.c., 1 c.c., and 1 c.c. at weekly intervals. As epidemiological evidence indicates that immunization with typhoid vaccine protects against infection for some time after vaccination, it is believed the assumption is justified that if the blood serum will protect against 1,000 m.l.d., the individual has suffi-

cient immunity to protect him against dosages of the organism ordinarily encountered in nature. Undoubtedly some, if not a large majority, of immunized persons whose blood sera will not protect mice against less than 1,000 m.l.d. are still immune to typhoid fever.

The data presented in Tables III and IV indicated that during the second year after immunization the blood sera of 69 per cent of a group of 56 persons, and 62 per cent of a group of 115 persons protected mice against 1,000 to 10,000 m.l.d. Also, that during the third year after vaccination the blood sera of 46 per cent of a group of 30 persons, and 35 per cent of a group of 93 persons protected mice against 1,000 or more m.l.d.

Not only does the degree of immunity produced by immunization with typhoid vaccine vary greatly in different individuals, in so far as can be judged by the mouse protection tests, but the duration of the immunity conferred by vaccine is also subject to wide variations. Because of these variations, it would be impossible to determine if any one person was immune at any given time, without testing his blood serum. However, it appears from the results of these studies that a large proportion of immunized persons are protected for at least 2 to 3 years after vaccination.

SUMMARY

Several groups of individuals have been studied with a view to determining, by means of the mouse protection test, the concentration of protective antibodies in the blood at intervals of time subsequent to immunization with typhoid vaccine.

Prior to vaccination, the sera of 79 per cent of one group of individuals tested failed to protect mice against 100 m.l.d. of a live virulent test organism, and 76 per cent of another

group failed to protect against 10 m.l.d. of the test organism.

Within 2 weeks after vaccination the antibody content of the blood sera tested increased rapidly to a comparatively high level. There was a relatively rapid decrease in circulating antibodies during the 2 year period subsequent to vaccination. Thereafter, the decrease was more gradual and 10 or more years after the last vaccination the antibody concentration in the blood was sufficient to suggest that a large proportion of the individuals tested still possessed considerable immunity to typhoid fever.

During the second year after vaccination, 69 per cent of one group of immunized individuals and 62 per cent of another group protected mice against 1,000 m.l.d. of the test organism. During the third year subsequent to immunization, 46 per cent of the blood sera of one group and 35 per cent of another group protected mice against 1,000 m.l.d. of the test organisms.

CONCLUSIONS

1. Experimental evidence based on mouse protection tests indicates that there is a material decrease in protective antibodies in the blood during the first and second years subsequent to immunization with typhoid vaccine.

2. The decrease in the protective antibody content of the blood is the greatest during the first 2 years after vaccination, and is comparatively slow thereafter.

3. The protective antibody content of the blood of the average individual for as long as 10 years subsequent to immunization with typhoid vaccine is sufficient to indicate that he still possesses considerable immunity to typhoid fever. The results obtained by this study suggest that persons who have been immunized with typhoid vaccine should be re-vaccinated from 2 to 4 years after initial vaccination.

RE-VACCINATION BY INTRACUTANEOUS INJECTION

Where immunization is employed to control typhoid fever in civilian com-

munities, or among troops, re-vaccination is usually considered necessary. It has been customary in re-vaccination against typhoid fever to use the same dosage of vaccine and the same methods of administering the vaccine as in original vaccination. That is, three subcutaneous injections of vaccine at about weekly intervals. This method is time consuming, and, not infrequently, in persons who have been vaccinated several times, causes rather severe reactions.

It is known that in immunizing against certain diseases other than typhoid fever, one dose of antigen will elicit an immunological response in previously immunized persons. In view of this, we have undertaken a study to determine if one dose of typhoid vaccine would stimulate the defense mechanism in previously vaccinated persons and, if so, the degree of response that results from such a stimulus.

A group of 100 individuals were each given one dose of 0.1 c.c. of typhoid vaccine (100 million organisms) intracutaneously in the arm or forearm. All had been immunized with typhoid vaccine from 2 to 10 years, or more, prior to re-vaccination. Some had received two or more courses of the vaccine.

Blood specimens were taken immediately before and 14 days after re-vaccination. The blood sera were titrated by the mouse protection test, using 0.1 c.c. of the individual's serum against multiple m.l.d. of the test organism (Strain No. 63 *supra*) for normal mice. The results are shown in Table V.

Before re-vaccination, the blood sera of members of this group protected mice against from 1 to 10,000 m.l.d. of the test organism. In 71 per cent of the observations the blood sera failed to protect mice against 1,000 m.l.d. and 21 per cent failed to pro-

tect mice against 100 m.l.d. (Table V-A).

After re-vaccination, the blood sera protected mice against from 1,000 to 100,000 m.l.d. In 76 per cent of the cases, the blood sera protected mice against at least 10,000 m.l.d. (Table V-B).

COMMENT

The results of a study of the protective antibody content of the blood sera of 200 individuals 2 weeks after original vaccination with a series of three injections of typhoid vaccine have been tabulated in Table II. It will be seen that in this group 20 per cent of the sera protected mice against at least 1,000 m.l.d., and 80 per cent of the sera protected against at least 10,000

m.l.d. In comparison, in the re-vaccination of a group of 100 persons with one dose of vaccine (0.1 c.c.) administered intracutaneously (Table V), 21 per cent of the blood sera obtained 2 weeks after re-vaccination protected mice against 1,000 m.l.d. of test organisms, and 76 per cent protected mice against at least 10,000 m.l.d. Three per cent protected mice against 5,000 m.l.d.

The results of these two studies are comparable, and indicate that the immediate immunological response to re-vaccination with one intracutaneous injection of 0.1 c.c. of typhoid vaccine is approximately the same as that which occurs after the first vaccination with three subcutaneous injections of 0.5 c.c., 1 c.c., and 1 c.c., respectively.

Re-vaccination with one small intracutaneous dose of typhoid vaccine has the advantage that it is, obviously, a much simpler procedure than is a method requiring three subcutaneous injections at weekly intervals. Also, the reaction is, almost without exception, much milder than that produced by subcutaneous injection of 0.5 c.c. or 1 c.c. of the vaccine.

In this study the reactions produced by the vaccine have been consistently mild and of short duration. The local reaction consisted of an area of redness at the site of the injection, and in a few instances slight swelling of the tissues. The most severe systemic reactions observed consisted of mild malaise, headache, and myalgia. Involvement of the axillary lymph nodes was observed in 46 per cent of the cases, headache in 20 per cent, and rise in temperature in 8 per cent. The highest temperature noted was 101°. In many instances, those presenting mild reactions following the intracutaneous injection of the vaccine had a history of relatively severe reactions after subcutaneous injections of the vaccine.

Data are not yet available which would permit the comparison of the immediate or long range immunological response to re-vaccination with one intracutaneous dose of typhoid vaccine with that produced by re-vaccination with three subcutaneous injections at weekly intervals. This phase is being given further study and will be made the subject of a future report.

The duration of immunity following re-vaccination with one intracutaneous injection of 0.1 c.c. of the typhoid vaccine has not been determined, but will be investigated in the future.

SUMMARY

A group of 200 persons who had never been vaccinated were given three subcutaneous injections of 0.5, 1 c.c. and 1 c.c. respectively of the typhoid vaccine. A group of 100 individuals who had received from one to several courses of the typhoid vaccine from 2 to 10 years or more prior to the time this study was made were re-vaccinated with one intracutaneous dose of 0.1 c.c. of typhoid vaccine.

Two weeks after vaccination, the blood sera of those re-vaccinated with a single dose of 0.1 c.c. of the vaccine intracutaneously and of those vaccinated for the first time with three subcutaneous injections of the vaccine protected mice against a virulent strain of *E. typhosa* to approximately the same degree.

The results obtained indicate that the immunological response of the individual to re-vaccination with one dose of 0.1 c.c. of vaccine intracutaneously parallels that following the initial vaccination with three subcutaneous injections of 0.5 c.c., 1 c.c., and 1 c.c. of the vaccine at weekly intervals.

The reactions observed following re-vaccination with 0.1 c.c. of typhoid vaccine are mild as compared with those frequently produced by subcutaneous injection of the vaccine.

CONCLUSIONS

1. Re-vaccination against typhoid fever of previously immunized persons with one intracutaneous dose of 0.1 c.c. of typhoid vaccine produces an immediate immunological response which is comparable to that following original vaccination with three subcutaneous injections of the vaccine.

2. As compared with re-vaccination with three subcutaneous injections of the vaccine, re-vaccination with one small intracutaneous dose of vaccine is a simple and time saving procedure.

3. The reaction following the intracutaneous injection of 0.1 c.c. of typhoid vaccine is relatively mild as compared with that frequently produced by the subcutaneous injection of 0.5 c.c. or 1.0 c.c. of the vaccine.

The Initiation of Social Medicine

STATISTICS indicate that professional, economic, and social factors influence mortality rates—a fact that has long been recognized, but until recently neglected by the medical profession.

Figures, quoted by Dr. René Sand in a paper presented to the Medical Society of Geneva, show that although mortality rates have been decreasing since the second half of the 19th century, the decrease has been proportional in all the social classes so the difference between the classes has varied little.

Public health and social medicine are becoming an increasingly important part of the medical curricula, as is shown by a survey of such courses in medical

schools. Eventually, it is believed, the medical course will be built around the normal person; the first year will be devoted to a study of normal physiology, followed in the succeeding years by courses in public health and by clinical work in which the social aspects of disease will be emphasized. The relationship of the medical profession to social medicine is yet to be established, but if the medical profession has had this training, the solution of the problem will be easier, happier, and quicker, and the individual members of the medical profession will be able to adapt themselves to the new situation more readily.—Dr. René Sand: *Revue Médicale de la Suisse Romande*, 18. 12:761-772 (Oct. 25), 1938.

Serologic Tests in the Diagnosis of Syphilis*

ELIZABETH MALTANER

*Division of Laboratories and Research, New York State
Department of Health, Albany, N. Y.*

THE Laboratory Section of the American Public Health Association has been interested for a number of years in the development of standard methods for the complement-fixation test for syphilis. Dr. Gilbert,¹ as referee, directed attention to establishing principles of technic, upon which leading serologists agreed, and which, if followed, might be expected to yield dependable results. So many phases of the technic rested upon a purely empirical basis that more complete information regarding the fundamental relationships that govern the reactions between the different reagents of the test was essential to further progress in standardization. After extended study, it has been possible recently to describe methods which permit a quantitative determination of the reaction and thus provide a rational basis for standardization of the test.²⁻⁴ Accurate measurement of the changes in complement activity that occur under the different conditions of the test depends upon the determination of the amount of complement required in each instance to give 50 per cent hemolysis, as well as upon the fact that constant and directly proportional relationships

exist between the increments of complement so required and the increments of serum or antigen used when these reagents are properly standardized and adjusted to give maximum interaction.

The new method was established as a routine procedure in the New York State Laboratory in April, 1937. The series of specimens⁵ provided by the U. S. Public Health Service[†] in its study to evaluate serodiagnostic tests for syphilis afforded an opportunity to study the results obtained in the "control tests" in comparison with those of the quantitative technic and of the method previously employed in New York State, which utilized the same reagents but was not quantitatively standardized.

The titer obtained by the quantitative method is the ratio of the amount of complement required for 50 per cent hemolysis in the presence of serum and antigen to that similarly required with serum alone. It is a numerical index of the activity of the serum. A titer of 1.0 indicates that the reaction of the serum is the same with or without antigen and a reaction of 1.5 indicates such a slight degree of activity that titers of 1 to 1.5 are

* Read before the Laboratory Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 26, 1938.

† We are grateful to Dr. R. A. Vonderlehr and Dr. J. F. Mahoney of the United States Public Health Service for making available the complete clinical histories of these cases.

TABLE I

*Results of Quantitative Complement-fixation Tests
Federal Series, 1936-37 and 1938*

Type of Case	Titer of Serum											Not Tested	Total
	1.0	1.1	1.2	1.3	1.4	1.5	1.6-1.9	2-3	4-6	7-10	10+		
Healthy persons	127	46	16	7	1	1	0	0	0	0	0	2	200
Syphilitic cases	30	6	1	7	0	1	10	34	121	54	129	14	407

reported as "no reaction." In general, titers greater than 6 correspond with a degree of reaction previously reported as "4+." In the test for syphilis titers may range from 1 to 500 or greater, but, as a routine procedure, only those up to 10 are differentiated; the higher ones are at present reported as "greater than 10." In the vast majority of cases, the discrepancy between duplicate determinations is less than 25 per cent and is usually less than 8 per cent.

The results obtained with 198 of the non-syphilitic and with 393 of the syphilitic groups that were studied quantitatively are given in Table I.

None of the sera from healthy persons had titers exceeding 1.5; in fact, only one was as high as 1.5. The cases from which the sera of the syphilitic group were obtained consisted mainly of treated cases in which the serologic reaction is frequently the principal evidence of the activity of the disease. One hundred and twenty-nine of the syphilitic sera had titers greater than 10; 54 of 7 to 10; 121 of 4 to 6; 34

of 2 to 3; 10 of 1.6 to 1.9; and 45 of 1.5 or less.

The results obtained with the specimens that were tested both by our previous method⁶ and by the quantitative technic are given in Table II and record the variations in the reactivity of the different sera, which the older method of testing and reporting failed to indicate. While the majority of specimens with titers of 7 or greater gave complete fixation in the old form of test, there were 11 exceptions, one of which was a marked discrepancy. Also, with other groups of specimens, which in the quantitative test were shown to have similar degrees of activity, the reports varied. For example, of 55 specimens with titers of 4 to 6, 9 in the older test gave slight or partial reactions (\pm or $+$), while 24 gave complete fixation (4+). These discrepancies, occurring as they did in tests made under similar conditions and with the same antigen, were evidently due to the fact that a method not quantitatively standardized fails to provide in every

instance conditions for maximum reaction and grades reactions in such a way that the reports have a quantitative connotation which is not always reliable. Fewer marked discrepancies in reports, however, were observed with the old test than with the methods of the "control" laboratories as shown in Tables III and IV which summarize their results in comparison with those

of the old and new methods of New York State. Discussion will be limited to those reports that must be considered widely discrepant; namely, the "doubtful" or "negative" reports on specimens with titers of 7 or greater, and the "positive" reports on specimens with titers of less than 2, since these are so striking as to warrant consideration in some detail.

° The reactions and clinical histories of these cases are listed at the end of this report.

The majority of specimens with titers of 7 or greater were reported as "positive" by all methods. However, "negative" reports were made on 6 and "doubtful" reports on 8 of these specimens. A description of the 14 cases is given at the end of this report. The serologic and clinical findings in 5 of these are reviewed briefly for purposes of illustration:

Case 273 F—Untreated *tabes-paresis*; titer greater than 10; all serologic reports positive except that of the Kline diagnostic precipitation test, which was doubtful.

Case 167 G—Syphilis of the central nervous system; no treatment; titer greater than 10; all serologic reports positive except those of the Kahn precipitation and the Eagle flocculation tests, which were negative.

Case 96 F—Latent; treated with two doses each of arsphenamine and bismuth; titer greater than 10; all reports positive except that of the Kline diagnostic test, which was negative.

Case 8 G—Cardiovascular; no treatment; titer over 500; all serologic reports positive except that of the Hinton precipitation test, which was negative. It is of interest that the Kolmer test was only moderately positive in this case which, of all those examined, had the highest titer in the quantitative test.

Case 70 G—Syphilis of the central nervous system with history of "4+" spinal fluid; untreated; titer greater than 10; all reports positive except that of the Eagle complement-fixation test, which was negative.

The clinical histories, as well as the results of the serologic tests, strongly suggest that the doubtful or negative reports made in these cases were attributable to faults in standardization which resulted in prozone effects.

Similar discrepancies occurred in reports of tests with specimens that had titers between 2 and 6 but, as mentioned above, these are not discussed since the conditions underlying the variations in each instance are not so apparent as in the case of the discrepancies of greater degree.

Titers of less than 2 represent such low degrees of reaction that the significance of each can be interpreted only in the light of the clinical signs

and history of the individual. Fifty-five specimens fall in this category. Forty-five had titers of 1.5 or less; 21 of these were negative in all tests and only one, No. 244 F, reacted to some degree in all. The cases in which the reports made by different methods were widely discrepant are listed at the end of this report. A review of the serologic and clinical findings in a few of them serves to illustrate the type of discrepancy that occurred.

Case 261 F—Symptomless; treated from May, 1934, to December, 1936: 14 doses neoarsphenamine, 16 bismarsen, and 61 bismuth intramuscularly; last treatment about one month ago; titer 1.3; all reports negative except those of both the diagnostic and exclusion precipitation tests of Kline, which were positive.

Case 277 G—Primary; between March, 1934, and February, 1938, the patient received 19 doses of arsphenamine and 27 of bismuth; titer 1.0; all tests negative except that of Kolmer, which was positive.

Case 256 F—Tertiary; although no treatment had been given, the reaction was negative in all except the Kahn presumptive and the Kline exclusion tests, which were positive.

Case 289 G—Primary; between August, 1927, and February, 1938, the patient received 62 doses of arsphenamine, 60 of bismuth, and mercury and potassium iodide for 12 months; titer 1.0; all reports negative except that of Hinton, which was positive, and that of the Kline exclusion test, which was doubtful.

In all, positive reports were made by at least one method with 18 different specimens in the group with titers of 1.5 or less. While in certain instances further information would be needed to determine to what extent the reports were discrepant, the general character of the clinical and serologic findings of the cases in this group was quite different from that of the discrepant cases in the group with titers of 7 or greater; clinically they were in large part well treated and the majority of the serologic reports were negative. Thus the findings, as a whole, suggested that any activity present was probably slight in

degree. Yet the "positive" reports made in such cases have the same connotation as those with sera of high degrees of specific activity when both are simply recorded as "positive" and, it would seem, would confuse and mislead the physician and certainly fail to give him complete information.

In occasional cases of syphilis, reactions may occur in certain tests and not in others, and the clinical signs or history may indicate less clearly than in the examples cited the nature of the discrepancies, so that the question arises whether the particular antigen is responsible for the reaction that occurs. In the tests for syphilis, the antigens that are used are very similar in nature so that when they are adequately standardized they might be expected to react in a uniform manner. The quantitative technic should be of particular value in the further study of such cases since it provides a means of determining readily the relative value of different antigens and thus affords a serologic control of different technics of complement-fixation or precipitation that has previously been lacking.

SUMMARY

In closing, it is important to stress several points which stand out clearly from a consideration of the comparisons made in this report. The consensus of the serologic results corresponded with those of the quantitative titration and with the clinical findings. The occasional doubtful and negative reports, however, which were made by the different methods with specimens of high titer in the quantitative test, suggest faults in standardization that result in prozone effects. Further, the practice of limiting reports to "positive,"

"doubtful," or "negative" not only does not serve the clinician adequately, but unfortunately, also fosters the trend for serologists to oversensitize the technic and to report as "positive" the results with sera of relatively slight or doubtful activity. Positive reports with such sera cannot have the same significance as with those of marked activity. Certainly, methods of reporting which fail to distinguish them are misleading to the physician. Finally, reports of "positive," "doubtful," or "negative" connote a laboratory diagnosis whereas the clinician has full responsibility and, with complete information, he, not the laboratory, should make the diagnosis.

It is believed that a quantitative evaluation of the specific activity of a serum which the new method of complement-fixation affords, provides a reliable basis for the standardization of serologic tests and should prove, with clinical experience, an essential guide to the more effective treatment and control of syphilis.

Case 68 G

Age 22; male, white

Diagnosis: tertiary latent; Bl. Kahn 4+

Treatment: Neo and Bi q. week past 4 mos.

Temperature: 98.6; last meal 2 hrs.

Titer: 1.1; all reports negative except those of the Kahn presumptive, and Kline exclusion tests which were positive, and the Kline diagnostic and Eagle micro-flocculation tests which were doubtful

Case 308 G

Age 25; female, colored

Diagnosis: secondary

Treatment: 3.9.37 to 2.21.38—15 Bi and 3 ars.

Temperature: 98.6; last meal 1 hr. 30 min.; 2 oz whiskey prior to collection of specimen; 2d day of menstruation

Case 64 F

Age 52; male, white

Diagnosis: latent, treated

Treatment: 3.17.36 to 1.4.37=14 bismuth salicylate 0.15 gm (m) and 6 bis. sod. tartrate 2 cc. (m); had 10 intramuscular injections from family doctor in June and July 1936

Temperature: 99; last meal 2 hrs. 45 min.

Titer: 1.0; all reports negative except that of the Kline exclusion test which was positive

Case 67 F

Age 59; female, white

Diagnosis: latent, treated

Treatment: 1.31.20 to 1.18.37 arsphenamine 0.4 gm (v) x 13; 9 mos. Hg. rubs and KI gtt 15 T I D; bismuth salicylate 0.15 gm x 35; neoarsphanamine 0.2 gm (v) x 2; several spinal drainages

Temperature: 99; last meal 4 hrs.

Titer: 1.0; all reports negative except that of Kolmer which was positive, and those of the Kline exclusion test and the Hinton test which were doubtful

Case 70 F

Age 44; male, colored

Diagnosis: latent, treated

Treatment: 1930=8 arm injections by local doctor; 1.28.31 to 11.18.36=bismuth salicylate 0.15 gm (m) x 104; 20 months of Hg rubs and Potassium Iodide gtt 15 T I D

Temperature: 98.4; last meal 10 hrs.

Titer: 1.0; all reports negative except that of the Kline exclusion test which was doubtful and that of the Hinton which was positive

Case 244 F

Age 60; male, white

Diagnosis: tertiary lues (hepatic); patient showed no signs of syphilis beyond a strictly positive blood test; spinal fluid findings negative; died February 3, 1937 of cirrhosis of the liver; no autopsy

Treatment: antiluetic treatment many years ago

Temperature: 98; last meal 4 hrs. 30 min.

Titer: 1.0; New York State report was negative; Hinton report was doubtful; all others positive

Case 256 F

Age 33; female, black

Diagnosis: tertiary

Treatment: none

Temperature: 99.8; last meal 2 hrs.

Titer: 1.0; all reports negative except those of the Kline exclusion and the Kahn presumptive which were positive

Case 59 G

Age 50; male, colored

Diagnosis: now has latent lues; infected in 1935; 4+ Wass.

Treatment: in 1936 26, in hip, Bi; 26 neo in arm

Temperature: 98.6; last meal 2 hrs.

Titer: 1.0; all reports negative except those of Kahn presumptive and Kline exclusion and Hinton which were positive, and Kline diagnostic and Eagle micro-flocculation which were doubtful

Case 69 G

Age 26; male, white

Diagnosis: tertiary latent; Blood Kahn 4+

Treatment: none

Temperature: 98.6; last meal 2 hrs. 30 min.

Titer: 1.0; all reports negative except those of the Kahn presumptive and Kline exclusion which were positive, and the Kahn standard and the Kline diagnostic which were doubtful

Case 277 G

Age 42; male, white

Diagnosis: primary, treated

Treatment: 3.21.24 to 2.11.38 received 19 ars. and 27 bi.

Temperature: 100.2; last meal 1 hr. 40 min.

Titer: 1.0; all reports negative except that of Kolmer which was positive

Case 289 G

Age 25; female, white

Diagnosis: primary

Treatment: 8.7.27 to 2.16.38 received 62 ars., 60 bi., and 12 mos. Hg. and Ki inoculations

Temperature: 99; last meal 8 hrs.

Titer: 1.0; all reports negative except that of the Kline exclusion test which was doubtful and the Hinton test which was positive

Case 300 G

Age 49; male, colored

Diagnosis: primary

Treatment: 1924 to 2.18.38, 18 ars., 10 Bi., and 2 mos. Hg and Ki

Temperature: 98.6; last meal 6 hrs.

Titer: 1.0; all reports negative except the Eagle complement-fixation test which was doubtful and the Hinton test and the Eagle microflocculation test which were positive

Case 311 G

Age 20; female, colored

Diagnosis: ? primary

Treatment: 10.30.35 to 2.21.38—41 ars., 41 Bi., and 6 mos. Ki+Hg

Temperature: 98.4; last meal 2 hrs. 45 min.; 2d day of menstruation

Titer: 1.0; all reports negative except that of the Kline exclusion test which was doubtful and the Hinton test which was positive

Case 121 F

Age 19; male, colored

Diagnosis: primary chancre without secondaries in which treatment had been

instituted on 3rd day of lesion, at clinic; Bl. Wass. 2+

Treatment: 6 intravenous neo before admittance to hospital with ischio rectal abscess and primary lesion involuting; 3 I.V. neo and 3 intramuscular bismuth since entry

Temperature: 98.6; last meal 4 hrs.

Titer: 0.9; all reports negative except Kahn presumptive and Kline exclusion which were positive and Kline diagnostic which was doubtful

Do We Save Life?

MY point is obvious: If we save a man from death by tuberculosis we save him for death by something else. We may postpone death but what we really save is health. That is eminently worth saving whether life be prolonged or no. Indeed the mere prolongation of life without the conservation of health may well become a disaster, social no less than personal.

. . . It is estimated¹ that by 1975 the population 20 to 44 years of age

will have increased by only 6 per cent but the population 45 to 64 years of age will have increased by 69 per cent. Unless the generation now in high schools and colleges can be delivered from the invalidisms of middle age they will become an intolerable burden upon their offspring.—J. Rosslyn Earp, *New York State J. Med.*, Dec. 15, 1938, p. 1560.

Nursing Service of the State Health Department*

As Seen by the Private Agency

ALMA C. HAUPT, R.N., F.A.P.H.A., AND
VIRGINIA A. JONES, R.N., F.A.P.H.A.

*Director, Nursing Bureau, Metropolitan Life Insurance Company,
New York, N. Y.; and Assistant Director, National
Organization for Public Health Nursing,
New York, N. Y.*

THE general aim of the nursing service of the state health department is to assist in the promotion of the health of all the citizens of the state. It accomplishes this aim chiefly by helping each locality to provide and maintain proper local nursing services of good standard. We see, then, the state health department nursing service as a standard making and promoting force, interested in both public and private agencies and concerned with maternity service, control of communicable disease, the care of the sick, and the health supervision of the well.

If the state nursing service is to fulfil its large responsibility toward local services, it needs to be part of a modern well set up state health department; to serve all of the bureaus of the department, and to be on terms of good relationship with each of them. Moreover, it needs qualified leadership, sufficient nursing personnel, and an adequate budget, in order to have an adequate program.

Such a state nursing service profits by close association with all other state-wide forces working for health—professional organizations covering such fields as medicine, nursing, education, home economics, and social work; and lay groups, especially those with formulated health programs.

We can also see the state nursing service as an essential link in the chain between local and national health services. The national agencies help to set standards, to develop principles of action, to make studies, and to outline programs. These are all done in the hope that they will extend and improve local health services, but the jump from a national to a local service is often too great. Increasingly, the state health departments are looked upon as the intermediary.

This brings us to a wish made by Katherine Tucker in 1932, "to have in each state department of health an adequate budget for a state public health nursing service which would provide for a well qualified personnel in sufficient numbers to carry on a public health nursing service requisite for each state."¹

* Read before the Public Health Nursing Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 26, 1938.

That wish is gradually being answered as a comparison of the situation in 1931 with that in 1937-1938 shows:

reau. Interest in the subject is reflected by the fact that we received replies from 100 per cent of our inquiries.

TABLE I

The Type of Public Health Nursing Organization in State and Territorial Health Departments in 1931 and 1937²

Type of Organization	1931	1937	1938
Separate bureau or division	9	21	26
Unit under central administration	2	7	6
Unit under local health work	3	5	5
Unit under division of maternal and child health	24	18	14
Total states and territories providing a public health nursing consultant service	38	51	51

Further progress is noted by a comparison of the 1931 report, "Public Health Nursing in State Health Departments" made by the National Organization for Public Health Nursing, with a report made in 1935 by a joint committee of the American Public Health Association and the National Organization for Public Health Nursing. In the foreword to the 1931 report Sophie Nelson says, "The material indicates that the practice is so variable that it is not possible to draw any conclusions which might lead to formulation of principles."³ The later study made in 1935 went a long way in developing a carefully prepared statement of the functions of nursing service in state health departments and tentative suggestions for performing these functions.⁴

Inasmuch as we have this excellent statement of functions and methods plus the many suggestions put forth by Miss Tucker and Miss Nelson in the papers already referred to, we are laying the emphasis in this paper on what the private agencies want of the state health departments, and how the states can or would like to fill these needs. Our paper is based on inquiries sent to 10 visiting nurse associations of varying sizes and widely distributed geographically. We also wrote 4 state health departments, the U. S. Public Health Service, and the U. S. Children's Bu-

What does the private public health nursing agency expect, hope for, and need from the nursing service of the state health department? Moral support! The director of a large eastern city agency says, "Because our state health department concentrates its services more in the rural areas it is difficult to know how the large private city agency should use it. However, it gives us a feeling of stability to know there is a good state health department behind us that will set the standards for all health work in the state."

Liaison agent! Another large city agency looks to the public health nursing division of the state health department to provide connection with nurses out in the state, if the agency wishes to take up any matter in an individual county.

"We use the state nursing staff of specialists in our program of staff education" says another large city service in the middle west. "We consult the Division of Public Health Nursing regarding possible applicants for vacancies on our staff and seek stipends for staff nurses who prefer to work in the rural field."

The smaller nursing service hopes for all the services that her big city sister wants and more! "We believe," says the director of a comparatively small agency in the deep south, "that another very helpful project would be a good

circulating library. This, of course, would consist of the current new professional books and should be kept right up to date."

"Naturally we small organizations cannot afford a maternity, tuberculosis, or mental hygiene supervisor," states a philosophic visiting nurse association director from the state where the tall corn grows. "It seems to me there is a chance for much help in staff preparation through the use of the special supervisors in the health department."

From the far Northwest where private agencies are few and far between, a small visiting nurse association uses the state health department "for help in devising better methods of working with and through lay committees."

Private public health nursing agencies, large and small, from east, west, north and south and in between, look to the state health department to set standards and furnish support in maintaining them. They seek help in improving their service through the state's leadership and participation in staff education programs. They want help in keeping up to date in special fields through consultant service available from the state health department. They look upon the state health department as an agency which can collect information, new ideas and accounts of interesting experiments, and distribute them through bulletins, libraries, institutes, speakers, literature, correspondence, and other means. They use this state-wide agency for a place to find nurses for jobs and jobs for nurses. They seek, in return for providing a practise field for new nurses, stipends for scholarships for their own staff nurses. One director of a large visiting nurse association on the Pacific Coast summarizes the ways in which the state health department could provide better service to the private agency as follows:

1. Assuming responsibility for placement of

public health nurses in the state, both in private and public agencies

2. Being ready to act in an advisory capacity to private agencies as well as public

3. Keeping communities informed as to trends in public health nursing and its administration

4. Sponsoring educational programs, institutes, and conferences in urban as well as rural areas

This is a big order for any agency. Can the state health department meet these demands?

The Division of Public Health Nursing in the State Bureau of Health in Maine states that all nurses in private agencies are included in the staff education institutes and are given the opportunity to participate in the discussions and in taking definite part in the program. "We would like to see better coöperation between the local private and official agencies themselves, and better reporting to the State Health Department of work accomplished."

"We have a lending library from which all nurses can borrow," reports the Chief of the Bureau of Public Health Nursing in Indiana. "Our *Public Health Nursing Manual* is available for all nurses who request it. All news bulletins of any kind go to all the public health nurses in the state. Nurses employed by private agencies are eligible for fellowships for further training in public health nursing which we have available through Social Security Funds. . . . We would like the private agencies to remember that the nurses in the State Health Department need the stimulation that the agency's consultants can give us through visits at our office, conferences in the field, and permission for our staff to visit their agency to gather new ideas. Don't forget that private agencies were the first to develop public health nursing services both locally and in state health departments." They also furnish most of the opportunities for student practice and observation.

"As you are probably aware," writes the Director of the State Division of Public Health Nursing in Oregon, "we have only one private agency in the State of Oregon giving nursing service. To that association we supply credentials of qualified nurse applicants and give advisory service concerning problems of organization and administration as needed. We hope the nurses on the staff feel they may participate more actively in our educational program and make wider use of our consultant service and library facilities."

New York State offers "an arbitration service for both official and non-official agencies with thought for the integrity of the nonofficial agency when certain critical situations or opportunities arise as, for instance, discouraging employment of nurses by welfare authorities when service for indigent persons could be bought from existing visiting nurse associations."

There is precedent and experience to prove both that private agencies have not looked and will not look in vain to the nursing services of state departments of health for the services they need and that the state health departments not only appreciate the rôle of the private agency in trying out and perfecting new ideas and in providing practise fields and experience for nurses needed so badly in rural areas, but also that they take very seriously their obligation to all agencies which are contributing to the public health program.

These statements would indicate that the staff of the state nursing services must act as counsellors, teachers, judges, vocational and placement secretaries, and leaders in public health nursing—in other words, they must be the best nurses in the country. Both private and official agencies have a responsibility for demanding the type of machinery that will assure the careful selection of personnel and provide suitable administration and security in the job so they

may contribute to their fullest extent.

Marion Sheahan, Director, Division of Public Health Nursing, State Department of Health in New York, writes:

A nonofficial agency thinking of the total health of the community is limiting its usefulness if it does not understand and influence the appointments of personnel capable of providing leadership for a whole program, working out the part of the whole program to which a nonofficial agency can best contribute and then continuing to influence the conduct of the program so there is an integrated community service. I believe this might even extend to the initiation of a nonofficial agency by the official agency leader where one is indicated but does not exist.

Pearl McIver, Senior Public Health Nursing Consultant of the U. S. Public Health Service, writes:

You will remember that I have believed for some time that the plan of organization in a state health department was not so essential as the attitude toward nursing of the commissioner and other division directors. However, our experience from the past few years has led me to believe that nursing should be organized as a separate bureau on a par with all other activities of the state health department. This does not mean that it would function as a separate entity. To be successful, it must be very closely correlated with the work of all other divisions. It naturally follows that there should be a strong person in charge of local health activities who will be the coordinator for the work of all divisions which have to do with local health services. This would include nursing, sanitation, child hygiene, tuberculosis control, syphilis control, dental hygiene, etc.

This statement ties in with the recommendation made in "Nursing in State Health Departments"⁴:

To coordinate service of all public health nursing in the department of health, a unit of nursing headed by a well qualified public health nurse, is necessary. The conclusion that a unit is needed has already been reached by the Inter-departmental Committee for Coordinating Health and Welfare Activities of the federal government.

Naomi Deutsch, Director, Public Health Nursing of the Children's Bureau, suggests another item for our discussion:

What provision for coöperation with professional groups of nurses is there in the health department, such as representation on board of health, representation on advisory committee or through an advisory committee on public health nursing.

This has reference to

... representation from public health nursing groups on advisory committees to the state health departments, such as the general advisory committee to the department and advisory committees to separate divisions, particularly those of maternal and child health, public health nursing, services to crippled children, etc. Such types of representation are being more and more encouraged and are quite prevalent in the maternal and child health services and services to crippled children.

It would seem then, that if the state nursing service is to be in a position to help the private agencies, a unit of public health nursing under qualified nursing direction is an essential. Also some plan for public health nursing representation on advisory committees makes for smooth coöperation. It is interesting to note that both of these essentials have been recommended by the National Organization for Public Health Nursing as far back as 1926.

We would like to suggest that the nursing staff of the state health departments develop a definite plan for visiting the private agencies, to review with them questions of organization, administration, staff education and program, both in terms of content and of the extent to which the program reaches into the community. And why not reverse the procedure by suggesting that the directors of the private agencies make a practice of visiting the state health department office once a year, or once every other year? Is it not important for us to see the set-up and review the program on the ground?

Let us pause here to speak in more detail of staff education. Is there any better way of developing a community viewpoint among local nurses than to bring together into a joint staff meeting

the members of the local public and private agency staffs? Should not each know the program, technics and teachings of the other? and should not the effectiveness of both services in qualitative and quantitative terms be studied jointly? It would seem that the state health department nurses were the logical instruments to bring this about.

Effective team work between private local agencies and the state nursing services depends on two factors. The first is that the state accepts the responsibility of helping the private agencies and is equipped to do so. The second is that the private agencies recognize the state nursing service as in a position of leadership, and request consultation and advice from it. Undoubtedly the states which are making greatest progress are those in which the public and private agencies, both local and state, have learned to play the game together. May their tribe increase!

In conclusion, let us look at the national picture. Since the passage of the Social Security Act, we have been tremendously strengthened by consultant public health nursing services in two governmental agencies, the U. S. Public Health Service and the Children's Bureau, each with 5 regional consultant nurses under excellent leadership from Washington. In addition, several private national groups are in the public health nursing picture. Among them are:

National Organization for Public Health Nursing

American Red Cross

National Society for the Prevention of Blindness

American Social Hygiene Association

Maternity Center Association

John Hancock Mutual Life Insurance Company

Metropolitan Life Insurance Company

Each of these provides nurses who visit the states and many of them visit local services within the states.

It would seem that the objective of each would best be reached if the work were carried on as much as possible through the state nursing services. Up to now, the opportunity for this has been limited by the limitations of the states themselves. Increasingly, we hope the state nursing services will be kept better informed of the programs and methods of each national group. This can be brought about in part by more frequent individual conferences between the representatives of national agencies and the state nursing staffs. One practical device is the sending of itineraries of national representatives to the states.

This question of the desirable interplay between private agencies and state nursing services presents many problems of relationships—local to local, local to state, state to national, and then the whole series in reverse order. This brings new emphasis to our need for and dependence on one national agency equally interested in us all—the N.O.P.H.N. Anew we realize that the National Organization for Public Health Nursing is a clearing house. Through it, we may all clear our ideas, our successes and failures; and from it, we get guiding principles and generally accepted practices which we in turn adapt to fit the needs of the locality or state.

In a general sense, the N.O.P.H.N. may be thought of as the operating part of the Public Health Nursing Section of the American Public Health Association. Through the Section we have the opportunity of participating in all other branches of public health work and of learning how to integrate our part with the whole. Through the N.O.P.H.N. we try to put public health nursing into successful operation.

We are in a period of great stimulation of public health nursing. There are new emphases, new methods, and new funds. Public and private agencies are both necessary, and upon their ability to play the game together will the aim of better health for all the people be reached.

Studies on Trichinosis*

XI. The Epidemiology of *Trichinella spiralis* Infestation and Measures Indicated for the Control of Trichinosis

WILLARD H. WRIGHT, Ph.D.

Senior Zoölogist, Division of Zoölogy, National Institute of Health, U. S. Public Health Service, Washington, D. C.

TWO years ago we inaugurated in the National Institute of Health a basic study designed to determine the extent of the trichinosis problem in the United States and to provide information which might aid in outlining a working program for the control of this disease. This study is based on the examination for trichinae of diaphragm material from cases coming to necropsy in hospitals, the cases representing routine hospitalizations unassociated with either clinical or anatomical diagnoses of trichinosis. Each diaphragm included in this study has been examined by two different methods, the direct microscopic method and the digestion-Baermann method, both of which have been described in detail by Hall and Collins¹ and by Nolan and Bozicevich.²

At this writing there has been examined a total of 3,000 diaphragms divided into several different series according to the origin of the material. These various series are, as follows:

1. A base series comprising diaphragms received from 10 hospitals in Washington,

D. C., 2 U. S. Marine Hospitals, and 4 U. S. Naval Hospitals on the east coast.

2. A random series comprising diaphragms received from 51 hospitals in 19 states, the hospitals being selected purely at random and the diaphragms representing random samplings of cases coming to necropsy in these hospitals.

3. A so-called "negative" series comprising diaphragms from certain hospitals in states in which no cases of clinical trichinosis had ever been reported.

4. A traumatic series comprising diaphragms from persons meeting traumatic death and not hospitalized, designed to negate the criticism that a previous trichina infestation may have influenced the hospitalization of some of the cases represented in the other series.

5. A Jewish series comprising diaphragms from orthodox and unorthodox Jews, designed to ascertain the value of the Mosaic Code in preventing trichinosis under complex modern conditions.

Table I presents the results of the examination of diaphragms in the various series.

The basic series comprising over 2,100 diaphragms at this writing shows a trichina incidence of 16.8 per cent, and the random and negative series show incidences of 18.3 and 18.6 per cent, respectively, figures which are within 2 standard deviations of findings in the base series. The traumatic series, with yet a relatively small num-

TABLE I

Results of Examination of 3,000 Diaphragms for *Trichinella spiralis*

Series	Number of Diaphragms Examined	Number of Diaphragms Positive	Per cent Positive
Basic	2,174	366	16.8
Random	436	80	18.3
Negative	140	26	18.6
Traumatic	116	16	13.8
	2,866	488	17.0
Jewish	134	1	0.7
Totals	3,000	489	16.3

ber of diaphragms, has an incidence of 13.8 per cent, a somewhat lower incidence than the other series. However, since positive findings fluctuate considerably from time to time in small samplings, there is reason to believe that this series will eventually show a percentage of positives close to the figure of the base series. If the Jewish series with a remarkably low incidence

of 0.7 per cent is omitted, it is noted that 17.0 per cent of the remaining diaphragms were positive for trichinae.

Our findings are in quite general accord with the summarized findings of trichina surveys conducted in various parts of the United States by other investigators. These findings are given in Table II.

In each of these surveys, with the single exception of that of Sawitz, only one method of examination was employed. Nolan and Bozicevich² have pointed out on the basis of our findings that either the microscopic method or the digestion-Baermann method used alone will detect only 66 $\frac{2}{3}$ per cent of the positive cases. If we apply a correction figure of 33 $\frac{1}{3}$ per cent to the total positives given in Table II, less Sawitz's cases, we have 594 positives, instead of 446 positives, in 3,294 diaphragms, or an incidence of 18.0

per cent. While there are several variables in the data given in Table II, such as differences in method, amount of material examined, and changing factors over the period of time represented, it is striking that the corrected incidence figure is in such close agreement with the incidence figure in our series.

The number of larvae per gram of diaphragm material has been recorded in connection with all of our examinations and Table III gives a summary of these findings. The great majority of the positive cases represented infestations with less than 11 larvae per gm. However, 2.5 per cent of the cases had infestations varying between 101 and 1,000 larvae per gm. Unfortunately, we do not know the degree of trichina infestation, as expressed in terms of larvae per gm. of muscle, which will result in clinical symptoms of trichinosis, and it is therefore difficult to translate our findings into terms of cases of the disease. Ferenbaugh, Segal, and Schulze³ found only 8 larvae per gm. of gastrocnemius muscle obtained on biopsy from an individual suffering from clinical trichinosis. However, it is doubtful whether an infestation of this degree would be sufficient to produce clinical symptoms of disease in all cases. Furthermore, we have little reliable data as to the relative extent of trichina invasion of various muscles. If 0.4 per cent of our present population is infested with 101 to 1,000 larvae

per gm., there would be several hundred thousand individuals who would have been ill at some time or other with clinical trichinosis. Obviously, this figure represents the roughest sort of estimate and can have no validity until we are in possession of a great many more data. However, the figure would seem to indicate the occurrence of recognizable cases of trichinosis vastly in excess of the 5,000 to 6,000 reported during the past 95 years.

INCIDENCE IN POPULATION GROUPS

In connection with our diaphragm studies, we obtained information concerning the sex, age, race, occupation, and social-economic status of each individual represented. These data are designed to provide information concerning trichina infestation in different population groups and to determine the validity of our incidence figure as applied to the general population. Table IV presents these data for 2,000 cases in our base series.

In order to arrive at a rational interpretation of the data in this table, we should first examine statistically the validity of our incidence figure of 17.1 per cent for these 2,000 cases. The standard deviation of our percentage of positive cases, as computed by the formula

$$\sqrt{\frac{pq}{n}}$$

TABLE III

Trichina Larvae per Gram Found in 489 Infected Diaphragms of 3,000 Diaphragms Examined

Group No.	Larvae per Gram	Number of Cases	Per cent of Cases
1	Less than 1	177	36.2
2	1 to 10	246	50.3
3	11 to 50	47	9.6
4	51 to 100	7	1.4
5	101 to 500	9	1.9
6	501 to 1,000	3	0.6
7	Over 1,000	0	0
Totals		489	100.0

where p is the percentage of positive cases, q the percentage of negative cases, and n the total number of cases examined is ± 0.84 . Thus, on repeated samples of 2,000 each of the type of material here sampled, we might expect a range of variation due to chance as high as 18.8 per cent and as low as

15.4 per cent, this range being the range of 2 standard deviations above or below the mean of the sample.

An examination of Table IV indicates that there is apparently no special correlation between trichina infestation and most of the population groups represented. The incidence figure for the

Unknown	14	1	7.1			1	0	0
Totals	2,000	341	17.1			128	50	163

following groups falls within the range of percentage variation possible by chance alone: white males, colored males, all males, colored females, all females, whites and negroes, Army personnel, civilians, occupation by land or sea, mentally deranged under hospitalization, mentally sound or not under hospitalization, high social-economic status and low social-economic status.

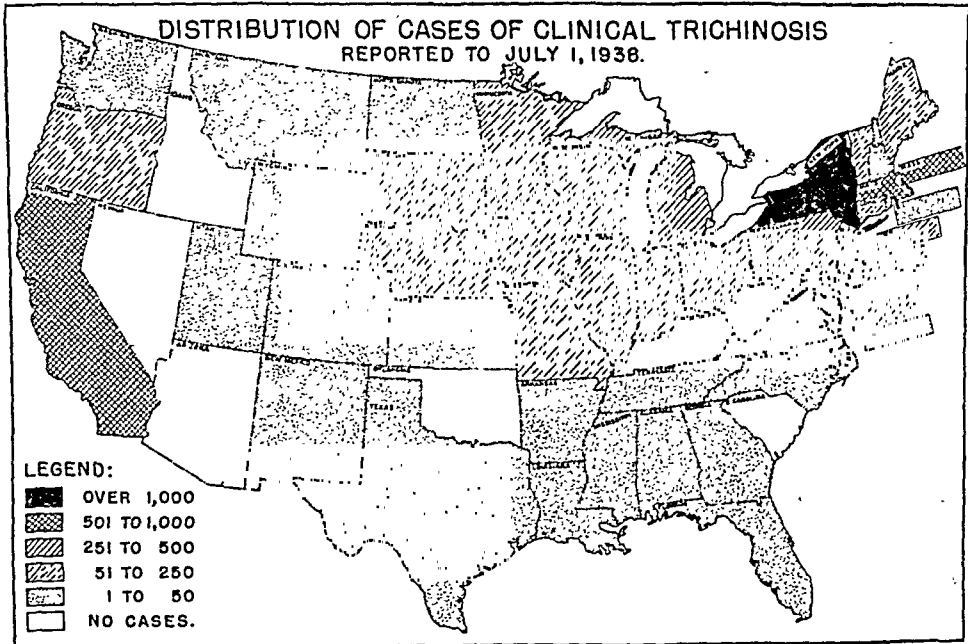

White females with 14.4 per cent infested are somewhat below the chance variation. However, the group is still rather inadequately represented and additional cases may bring the incidence figure more in line with the general incidence. The percentage of positives in the military group is slightly below the range of chance variation and a high incidence in commissioned officers is more than overbalanced by a low incidence in enlisted men and Navy personnel, the latter represented as yet by a relatively few cases. The percentage of positives in the veterans' group, consisting mostly of World War veterans, is 19.6, a figure higher than the 2 standard deviations from the mean percentage. However,

this group is made up of individuals with ages falling predominately within the decade 41 to 50. As the percentage of positives for this general age group is 19.2 (Table V), it would appear there is no particular correlation between past military service and trichina infestation.

There is one correlation which has not been computed from our data, but which is evident from information furnished by reported cases of trichinosis. There appears to be a very definite correlation between certain geographical areas and trichina infestation. Figure I shows the distribution of cases of clinical trichinosis reported up to July 1, 1938. The heaviest incidence areas lie along the North Atlantic seaboard and along the Pacific coast, areas in which the feeding of uncooked garbage to swine is extensively carried on.

Table V gives the incidence and state of trichinae by age at death for 2,000 cases in the base series. While the number of positive cases in the first two and the last decade is entirely too low to establish a sequence, in general there is a rise in the incidence of trichina infestation with increase in age.

FIGURE I

Such a sequence would be expected if we assume that long life offers greater opportunities for acquiring infestation. However, the decade 51 to 60, with 327 cases represented, shows an incidence of only 15.9 per cent, an incidence lower than that of the two previous decades. Furthermore, although the group incidence in ages 51 to 100 is higher than that in the age groups 0 to 50, both of the incidence figures fall within the range of chance variation of the series incidence. At this time, correlations between age and trichina infestation are not convincing and a larger series of cases must be awaited for support of the theory that individuals in later life should be more frequently infested with trichinae.

Considering the state of trichinae at age of death, infestations with mixed live and dead trichinae and with dead trichinae appear first in the decade 21 to 30, and in general the percentage of dead trichinae increases with increase in age. Such a trend might well be expected since relatively long life would permit of death and calcification of trichinae acquired in earlier decades.

SOURCES OF INFESTATION IN HUMAN TRICHINOSIS

With the exception of a small number of cases due to the consumption of bear meat, human trichinosis rests entirely on the basis of swine trichinosis. It is pertinent, therefore, to inquire into the source of infection in swine.

During the past 50 years or more considerable data have been accumulated concerning the prevalence of trichinae in swine fed on different types of feed. These data have been adequately summarized by Hall⁴ and need not be repeated in detail here. They may be expressed briefly as shown in Figure II.

Swine fed on cooked garbage and southern swine raised generally in fields and woods and without easy access to garbage or kitchen scraps rank in the lowest order of importance as sources of human trichinosis. Only about 0.5 per cent of these swine have been found to harbor trichinae.

Next in the order of importance are so-called grain-fed swine, as represented largely by swine from the Central West, of which 1.0 to 1.5 per cent have been

found infested with trichinae. If we exclude the rat as a major factor in the causation of swine trichinosis, it is apparent that these so-called grain-fed swine have not been raised exclusively on grain or on pasture crops but that many of them have received some garbage, probably in the form of scraps or swill from the farm kitchen.

Swine fed on uncooked garbage rank next in the order of importance as a source of human trichinosis and probably today represent the chief source of the disease in man. Since 4.5 to 5.0 per cent of these swine are infested with trichinae, they are approximately 10 times more important as a source of trichinosis than are southern swine and swine fed on cooked garbage.

Evidence indicates that swine fed on slaughter-house offal are very frequently infested with trichinae, since

these swine show incidences of trichinae of 10 to 20 per cent. However, the practice of feeding offal to swine has been largely discontinued and this discontinuance, merely as a result of general improvements in sanitation, represents one of the few advances made in the control of swine trichinosis in this country since the disease was first recognized.

It is my opinion that the rôle of the rat as a source of swine trichinosis has been largely over-emphasized. Evidence for such emphasis seems to be based chiefly on the examination for trichinae of rats killed or captured around garbage feeding plants. While it is true that such rats have been found to be frequently infested with trichinae, and that swine do eat rats occasionally, and do occasionally eat carcasses of other swine, such occur-

FIGURE II

RELATIVE IMPORTANCE OF DIFFERENT TYPES OF SWINE AS SOURCE OF HUMAN TRICHINOSIS

rences are not sufficiently frequent to account for the relatively high incidences of trichinae in garbage-fed hogs. If the rat were a major factor in the causation of swine trichinosis one would expect to find as great a prevalence of trichinae in swine fed on cooked garbage as in those fed on uncooked garbage, since there is no reason to believe that rats are less prevalent around plants feeding cooked garbage than around plants feeding uncooked garbage. Garbage is usually handled so carelessly around hog feeding plants that in most places rats would have easy access to uncooked garbage even though the hogs might receive only cooked garbage.

THE PROBLEM OF CONTROL

Today in the United States only two measures are being employed generally to prevent human trichinosis and neither of these methods is aimed at the prevention of swine trichinosis, which we have seen is the source of nearly all cases of human trichinosis. One of these consists in efforts to warn the public by press releases, pamphlet distribution, radio programs, etc., to cook pork well. While such efforts are well intended, and should be continued, they apparently accomplish little since during the past half century there has been no apparent decline in the incidence of trichina infestation in man and no decline in the number of reported cases of clinical trichinosis.

The second control measure is represented by that portion of the meat inspection regulations of the federal Bureau of Animal Industry requiring the freezing for 20 days at 5°F., the heating at 137°F., or the smoking or curing, or both, of pork products customarily eaten without cooking by the consumer. Such products are mainly of the variety of so-called summer sausages. These regulations are adequately enforced, and are adequate

safeguards against the contraction of trichinosis from such of these products as are federally inspected. However, since only approximately two-thirds of the meat consumed in the United States is federally inspected, this measure does not represent a general measure of protection against trichinosis.

Other than the measures now being used to combat trichinosis, the following procedures are open to us:

The microscopic inspection of pork for trichinae might be carried out as it is in Germany and some other European countries. However valuable this measure may be in reducing the number of cases of trichinosis over a period of years, it is an expensive procedure and one not geared to the high speed operation of American packing plants. The cost of carrying on microscopic inspection of all swine slaughtered in federally inspected plants would no doubt exceed the present costs of the federal meat inspection service.

The refrigeration of all pork at 5°F. for 20 days in order to kill trichinae would no doubt result in a fairly adequate sort of control. However, such a procedure would require greatly increased facilities for refrigeration and would no doubt add considerably to the cost of pork to the consumer.

The feasibility of using the intradermal or some other antigenic test for detecting trichinous swine immediately before slaughter is being investigated, with the idea that the refrigeration of such pork to kill trichinae would not constitute a prohibitive expense. Even if such a test were infallible, its application could be enforced only in federally inspected plants, thus leaving about one-third of our meat supply unchecked for trichinae.

In contradistinction to the costly or inchoate methods mentioned above, we still have immediately available an entirely feasible and practical plan for the control of trichinosis. Since the

hog fed on uncooked garbage is today the major source of human trichinosis, the most logical approach to the problem seems to consist in the control of garbage feeding. However, before any restrictions are placed on garbage feeding, those engaged in the practice should be given the opportunity of voluntarily instituting effective measures for the prevention of swine trichinosis. In the case of those who do not choose to coöperate voluntarily, other steps should be taken.

The situation calls for local and state laws and regulations providing for the licensing of garbage feeding plants, for the cooking of garbage for a period of time sufficient to destroy all trichinae, and for the supervision of such plants by the proper agency. Licenses should be granted to such existing plants as represent a considerable monetary investment but should be refused for new ventures and for small scale garbage feeders who have little financial stake involved and would suffer little or no financial loss if forced to discontinue the practice.

This is a bare outline of the first step which can be taken under existing conditions toward the control of trichinosis. Details can be worked out to meet local conditions. In some states, existing laws and regulations may provide sufficient authority for a program of action; in other states, it may be necessary to ask for suitable legislation.

In conclusion, it may be pointed out that such a program for trichinosis control will not approach efficiency unless some steps are taken by local health officials to clean up their own backyards. There is no doubt that many American municipalities are contributing directly to the spread of trichinosis through sanction of the practice of feeding uncooked municipal garbage to swine maintained either on farms operated by the municipality or on farms operated by private contractors.

While it is difficult to obtain up-to-date information on the extent of this practice, the *Municipal Index* for 1930⁵ gives data on garbage collection and disposal in 557 cities of over 4,500 population, of which 216, or 38.8 per cent, disposed of their garbage by feeding it to swine. Eddy⁶ has recently stated that this method is the one practised in the greatest number of cases, and Toquet⁷ has estimated that 50 per cent of cities with a population over 15,000 utilize the hog-feeding method of garbage disposal. Gillespie and Reinke⁸ reported that in 1930, 162 of 242 cities in California were disposing of garbage by feeding it to swine. In this connection it will be remembered that of all states, California ranks second in the number of reported cases of trichinosis.

As much of the pork fed on municipal garbage is slaughtered locally, swine maintained on uncooked city garbage are an important source of trichinosis within the municipality.

Milestones of the Past Fifteen Years in Public Health Nursing*

DOROTHY DEMING, R.N., F.A.P.H.A.

*General Director, National Organization for Public Health Nursing,
New York, N. Y.*

1923! Let me set the stage for the birth of the Public Health Nursing Section of the American Public Health Association whose fifteenth birthday we are celebrating.

It was the time of the "Health Fairy," of "Cho-cho" the health clown—the brain-child of the Child Health Organization; of tonsil clinics in rural areas where wholesale tonsillectomies were performed in schools, homes, and churches; of "open-window" school rooms; of courses in tuberculosis nursing and "specialized" tuberculosis nurses; of arguments for "generalization" as against "specialization"; of a high infant and maternal death rate being valiantly challenged by funds provided by the Sheppard-Towner Act. We find in a magazine the last picture of a horse carrying a public health nurse in a "buggy" on her country rounds and read that the occasion of the picture is one for lament as the Nursing Committee is selling the mare to buy a Ford—with tears on the part of all (maybe not the mare). The last stories of post-war work in France and Italy were being published; three university schools of nursing had been established at Minnesota, Yale, and Western Reserve. It

was the time of demonstrations: the Commonwealth Fund, the Milbank Memorial Fund, the Metropolitan Life Insurance Company. We note with sympathetic understanding an address at an A.P.H.A. meeting by a forward-looking health officer who demands: "After the Demonstration—What?"

The American Child Hygiene Association and the Child Health Organization combined in this year to become the American Child Health Association to lead an honorable life until the close of 1935. Councils of social agencies were creeping over the land and state laws of public health nursing were being reviewed and modernized. There were 35 states with state supervising nurses in their departments of maternity and infancy—thanks to the ways and means provided by the Sheppard-Towner Act.

In this year—1923—the American Public Health Association met in Boston, and the Public Health Nursing Section received its christening from the Governing Council of the A.P.H.A. Of its birth Margaret K. Stack,¹ then doing public health nursing in Connecticut, writes:

The reasons for this decision (to recognize the Section) on the part of the Governing Board of the American Public Health Association are due, we believe, first, to the good prenatal care the Section received in advice and help from the Board and various members who urged the development of such a

* Read before the Public Health Nursing Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 25, 1938.

Section, second, to the earnest desire on the part of the Section itself to be so well born that it would be of real help to the parent body.

There is some misunderstanding in the minds of both health officials and public health nursing regarding many points that have to do with the development of a public health nursing service. In some instances this is due to lack of knowledge on the nurse's part of the problems in administration of which the health officer may not approve but which he cannot change, and in some instances is due to the fact that the health official does not always realize that the public health nursing group has a contribution to give other than the actual nursing service it renders. It seems logical, therefore, that the American Public Health Association, which includes among its members a large number of health officers, both state and local, should be the clearing house for discussion of all such problems.

Lest there be a thought in the mind of anyone that the Nursing Section in this Association means building up another nursing organization, banish the thought. The only reason for a "Nursing Section" of this Association is because in no other organization of which we know is the opportunity given for the health officers and the public health nurses to meet as members and coworkers, and by fair and free discussion arrive at decisions that will be of help to all.

When it was a year old, the Public Health Nursing Section listed 125 members at its first formal meeting. It is quite significant, I think, that one of the first papers presented to this Section was on the relation of the public health nurse to the practising physician.

Moving on to 1924, we find the Delano Red Cross nurses starting their work in rural areas. We find from the N.O.P.H.N. Census of that year that there were 11,171 public health nurses in the United States. In that year, standard report forms were published; the administration of insulin, discovered in 1922, was becoming a problem to the visiting nurse services. The question of amalgamation of public health nursing services in a given community was being widely discussed. Community chests were gaining in popularity.

By 1925, the Public Health Nursing Section was trying out, for the first time, joint sessions with other A.P.H.A. Sections and with considerable success, judging by the attendance. The first joint session was held with the Health Officers Section. Lest we think the subjects we now discuss are fresh and new, let me record two of the subjects discussed 13 years ago: "The division of responsibility between the public and private agency"; "How far is nursing care the responsibility of public health nurses in the health departments?" On the former point, I note that Dr. Lee K. Frankel brought a round of applause by his cryptic remark that he "hoped for a measure of respect between the health department and the private agency!"

In the general field in 1925 we find all child health problems very much to the fore. Plans for the White House Conference had started. Child labor conditions were rousing the nation to action. In this year the John Hancock Mutual Life Insurance Company established its nursing service. In the foreign field, a public health nursing committee had been appointed by the International Council of Nurses.

Mental hygiene and social hygiene programs in connection with nursing services were becoming the fashion of the day. At this time the first minimum qualifications for appointment of public health nurses were published by the N.O.P.H.N. and a survey of 17 plants where industrial nursing was being carried on was undertaken and published. The N.O.P.H.N. made its salary study an annual routine. The problem of Civil Service appointments occupied the thought of both health officers and public health nurses in our Section meetings, and the problem of generalized and specialized services was still with us. In this connection, a note from Miss Fox's report of a conference at the Children's Bureau has a familiar ring.

She writes: "That the Children's Bureau is appointing a committee to consider nursing reports from the field because of the difficulty the Bureau has had in giving acceptable accounting of the Maternity and Infancy work done by nurses in generalized services." The committee consisted of two state directors of public health nursing, representatives of the Red Cross, a nurse with county experience, and Children's Bureau representatives.

In this year also it is rather surprising to find, for those of us who were not following federal activities closely, that the need for more effective coördination among the departments in government was being considered. I quote from an article² in the *Public Health Nurse*:

The need for the more effective coördination of these scattered branches of the government which are concerned with public health is apparent. Duplication of effort, to be sure, is not as great as might be expected, but there is some, and there would be much more efficacious operation if there were a central federal organization in the health field. During the last twenty years or more, a national department of health has been recommended, and several notable, but unsuccessful, attempts have been made to secure such a department or bureau. There once was, in fact, a National Board of Health, established by Congress in 1879 for a four-year period. Its activities were restricted in 1882, it received no appropriations after 1885, and the law creating it was repealed in 1893. The Sixty-eighth Congress, which adjourned last March [1925] had before it a plan for a new Department of Education and Relief, regarding which fortunately no action was taken, as the scheme was defective for many reasons. Whether a new department of health should be advocated at this time is a question of political expediency, but certainly there should be a correlated health service, at least under an assistant secretary or a commissioner.

... It is to be hoped that a practical plan for correlation of federal health activities will be produced shortly and that when it is and has been decided upon by the medical, sanitary, and nursing professions, and by experts in political science, Congress may be induced to act favorably upon it. Congress should,

therefore, be rather positively informed that they do.

We might claim I think that in 1938 Congress *was* "rather positively informed that they do."

1926. For some reason for which I am not bright enough to find a pre-disposing cause, 1926 was a momentous year in public health and nursing work. We had the Goldmark Report on Nursing Education; the Frontier Nursing Service (1925) got under way; the Grading Committee started; Joint Vocational Service began as an independent vocational placement and guidance bureau; the Harmon Association for the Advancement of Nursing inaugurated its annuity plan for nurses; the first cost studies for public health nursing were published; Dr. Ferrell studied and reported on 298 full-time county health units (a jump from 4 in 1911). We find the first *Journal* articles discussing the distribution of the nurse's time, and time studies. We find in the Public Health Nursing Section of the A.P.H.A. a discussion of reasons for the health department carrying on bedside nursing care, and, incidentally, one of the most interesting reasons I find to be the advantage of a closer relationship to the private physician, since "it gives an opportunity to make him understand and feel the importance of the health department work and show a new usefulness of the department to him." Regional conferences of state nursing supervisors were held in this year. And perhaps, as a most outstanding "Milestone," the National Health Congress was held at Atlantic City. All the national health agencies and many allied groups with health interests met in Atlantic City at that time. I find that we have recovered from that experience sufficiently to consider the possibility of a similar congress during the World's Fair in 1939!

1926 and 1927 were also agitated by the problem of advisory committees for public health agencies. At this time, the committee to study this question which had been appointed by the American Public Health Association and the National Organization for Public Health Nursing made its report, strongly urging the appointment of advisory committees which might preferably be called "Citizen's Committees" for local health department programs. Specific advantages were quoted for the existence of such committees: They maintained unbroken policies in spite of changing personnel; it was possible to free new appointments from political influence; the voluntary committee could demand higher standards; and finally be very influential in interpreting and winning support for the health department program among the citizens of a county or community. The N.O.P.H.N. seems to have been considerably exercised about this recommendation to the point of calling its Advisory Council together to endorse the committee's report and to urge the appointment of such groups. The Advisory Council also discussed at some length the relation of the public health nurse to the health officer and the N.O.P.H.N. was given a charge to develop such national relationships within the health field as would strengthen the hand of the public health nurse locally. I note that in this year the Maternity Center Association experimented in a rural delivery service in Tioga County, N. Y., with the help of Sheppard-Towner Funds. The first institute for board members was held in New Haven in the spring of 1927 which led to the eventual establishment of the Board and Committee Members' Section in the N.O.P.H.N. with a full-time secretary and the *Board Members' Manual*, published in 1930 and revised in 1937.

1927 saw the great Mississippi flood.

In 1928 the first appraisal form for public health nursing appeared. At this time, also, "Nurses, Patients and Pocketbooks" pointed out the oversupply of unqualified nurses being graduated from small schools of nursing. Hourly nursing was coming to be more or less familiar to the visiting nurse services and, internationally, we welcomed the appointment of a public health nurse to the Health Committee of the League of Nations.

Shall we pass lightly over 1929-1933? Or is it worth while to find out something of what happened in those years? Historians say that a true perspective can only be gained on a world event from a distance of 50 years, and we are looking at it within a 10 years period! However, there are certain outstanding points in this period whose imprint is left with us. It is well perhaps to summarize these.

The number of public health nurses increased. Work increased. In 1933, 1,882 unemployed nurses were put to work on part-time jobs, some of which became permanent. Salaries decreased, cuts in special services within agencies had to be made in many instances. Our relation to social work and relief was clarified. The federal government, stepping in to relieve the unemployment situation and supply medical and nursing care to the indigent who were on relief, recognized for all time the policy that medical care includes nursing care and agreed that public health nursing agencies supplying nursing care to those on relief should be paid on a "per visit" basis for such service, just as the doctors were being paid for their care to relief clients. There were many new types of positions opening at this time in federal and state health departments. The U. S. Public Health Service recognized the Minimum Standards for Appointment of Nurses in official positions recommended by the N.O.P.H.N. The

development of the state programs brought to the fore problems of the place of the nursing division in the department of health, and we find Dr. Arthur P. McCormack discussing this in one of the meetings of the Public Health Nursing Section. In 1929 a study of nurses in industry was carried on, and in 1930 a study of negro nursing. Qualifications for positions were published again in 1930 and 1935 and the objectives of public health nursing defined.

It is interesting to recall that in this time when so many unqualified nurses were being brought into the public health field, there were three basic requirements urged upon all communities employing this type of worker. You remember we said that the qualifications of the worker should be passed on by a professional committee before employment, that there should be qualified supervision of such workers, and that a period of introduction to the field should be given. The development of possible service from subsidiary workers and visiting housekeepers was and is still a matter of discussion.

The depression is reflected in some of the titles of topics discussed at the A.P.H.A. meetings. "Getting Public Health Nursing Needs Across to Appropriating Bodies," and "Fitting Public Health Nursing into the Budget." Other related subjects were: "The Use of the Layman," "A Study of Volunteer Workers," "Health Insurance Plans for Families," "The Development of Community Nursing Councils," the question of "Public Support to Private Agencies," and "The Purchase of Nursing Service from Private Agencies." The better coordination of all programs for economy's sake was in our minds during these years.

The N.O.P.H.N. Census in 1931 showed 15,915 public health nurses in the United States.

In 1931 Miss Nelson was engaged as Consultant to the U. S. Public Health Service—a period of study which led to her recommendation for the appointment of a public health nurse in the Research Division of the U. S. Public Health Service.

In general, other events were taking place: Nurses were being employed as hostesses on the air lines; certification of nurses in states was becoming more frequent. In 1933 the Birth and Death Registration Area was complete for the United States. The Public Health Nursing Section appointed in 1933 a committee to study nursing in state health departments. In 1933 also a report was submitted on "Public Health Nursing Throughout the World" from the International Council of Nurses.

Out of the depression we see other lines of interest leading to the future—the 5 day week, annuities for nurses, expansion in state supervisory work and county work, new routines for referral to clinics, the relationship of private agencies to the medical profession, and we see, through the President's own interest, a development in the work for crippled children.

In 1934 the "Survey of Public Health Nursing" brought clearly before us our shortcomings as teachers, and "Physical Defects—The Pathway to Correction" (a study among school children in New York City) revealed the gaps in the school nurse's program. Institutes were started to assist nurses in the field to supplement their knowledge and enrich the content of their visits. By this time the discussion of generalization versus specialization was dying out and generalization seemed to have come to stay.

By 1935 all of us were ready to see more vigorous leadership toward a national health program develop from Washington and in 1935 the Social Security Act was passed. In the U. S.

Public Health Service and the Children's Bureau qualified public health nurses began guiding the state nursing programs—with 10 regional supervisors to assist them. At this time also the National Health Survey was undertaken. At this date every state but one in the Union had a state supervising nurse in the state department of health. We became aware of a growing emphasis on bedside care of the sick and the hope that this care could be extended to the rural areas; pneumonia campaigns started and the orthopedic program got under way. The N.O.P.H.N. Orthopedic Council was established the following year.

In 1936 the A.P.H.A. reported 81 fellows and 456 active members in the Public Health Health Nursing Section. A committee was appointed that year to study the relation of official agencies to private programs and another committee to review possible projects for research. Of the Social Security Act, Miss McIver, holding the position of Senior Public Health Nursing Consultant in the U. S. Public Health Service writes:

The Social Security Act is not an emergency measure. It is designed for the purpose of developing a permanent program of social betterment. However, the appropriations authorized by the Act must be made by Congress on an annual basis. Whether Congress will continue to appropriate the funds authorized by the Social Security Act will depend in a large measure upon the results which are accomplished. Increased opportunities always mean increased responsibilities. Federal, state, and local health agencies which are responsible for the administration of this program must accept the challenge and show that they are capable of doing a good job. If all health workers—including health officers, engineers, nurses, and others—accept as a common objective *the development of a well rounded public health program*, and if all personnel are appointed on the basis of merit and not because of politics or personal favoritism, it will not be difficult to convince appropriating bodies that public health is both a social and economic necessity.³

In 1937 Miss Randall's study of personnel practices in official agencies was published ("Personnel Policies in Public Health Nursing"). Under Dr. Parran's leadership, the national syphilis program was well under way, and a conference on syphilis was held in Washington.

In 1937 the N.O.P.H.N. had its Silver Jubilee and a record membership. Noteworthy also was the first occasion on which the N.O.P.H.N. met officially with the A.P.H.A. at its New York City meeting.

I cannot go on to 1938 and a summary of this 15 year period without stopping a moment to record the loss of three leaders in the public health field whose passing crippled public health nursing. I have chosen only three since they were leaders in their particular line of activity. In 1925 we lost Anne Hervey Strong, R.N., in 1931, Dr. Lee K. Frankel, and in 1934, Dr. William H. Welch. These friends of public health nursing contributed far more than we realized at the time. Their names, I think, should be inscribed with honor on any record of the past 15 years.

1938, like 1923, 1926, and 1935, would appear to be a year in which a larger "Milestone" should be erected, for in January of this year the National Conference on the Better Care of Mothers and Babies was held in Washington, and the National Health Conference in July. The significance of the latter gathering only the future will reveal. We already know that the character of the gathering and the trend of its thinking and its influence on medical programs are without precedent.

During all these years we have seen an increase in the things which we desire most—the number of nurses, their standards for appointment, the quality of their service, the distribution of their

services. There are 23,271 public health nurses in the United States this year. We have seen our conception of the number of nurses needed by the country change from 1—2,500 to 1—1,800. We are on the verge of seeing a new coördination between the public and private agency of new plans for the prepayment of medical and nursing care. We have seen the Public Health Nursing Section grow from 125 members to 731 today—a strong consulting and consultant body closely related to the other Sections of the A.P.H.A. and ready to take its part in whatever activity of the Association touches public health nursing. We hope the Section will continue to serve as it was originally planned, as a “clearing house for all problems that concern the health officer and the public health nurse” for their mutual benefit and the ultimate benefit of the public whom we both serve.

What of the future? This was not in my assignment, but I am tempted to quote a statement from the report of the National Resources Committee published in May, 1938, which reads as follows:

Any advance in public health will depend upon the quality of scientific research, the efficiency of organization and administration of health services, and the adequacy of economic support of these services.

I can think of no better goal for the Public Health Nursing Section of the A.P.H.A. than to share through the A.P.H.A. in promoting these three essentials to the advancement of public health.

Dextrose in the Food Industries and Its Health Status*

CARL R. FELLERS, PH.D., F.A.P.H.A.

Nutrition Laboratory, Massachusetts State College, Amherst, Mass.

DEXTROSE † or refined corn sugar is a relatively new sweetening and preserving agent in the food industries. It was not until 1922 that Newkirk^{15, 16} made possible the commercial manufacture of dextrose by his special crystallization process.

Refined dextrose is made by converting highly purified starch with hydrochloric acid. After the conversion, the excess acid is neutralized with sodium carbonate and the neutralized liquor is passed through centrifugal machines, filter presses, and bone char filters to remove all unconverted substances. The clarified liquor is concentrated in triple effect vacuum pans to 30° Bé and again passed over the bone char for further clarification and to remove any dissolved coloring matter. This liquor is then concentrated to

a heavy gravity in the finishing vacuum pan. The heavy gravity liquor is put in large cylindrical crystallizers, and slowly agitated for from 90 to 100 hours. During this agitation, crystallization takes place.

The heavy liquor, containing the crystals of pure dextrose, is run into centrifugal machines which separate the crystals from the liquor. The crystals are washed with pure water until nothing remains but the crystallized dextrose.

The crystals are then removed from the centrifugal basket and delivered to hot air rotary dryers where the excess moisture is removed. The sugar is then screened and is ready for packing.

The sugar made by the above process is 99.5 to 100 per cent pure dextrose.

* Contribution 322 Massachusetts Agricultural Experiment Station, Amherst. Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 25, 1938.

† Also known as d-glucose, hydrated dextrose, dextrose hydrate, anhydrous dextrose and cerelese.

Until dextrose was accepted by the U. S. Pharmacopoeia, 10th revision in 1926, it was commonly known by the synonym "glucose." This confusion of names is unfortunate for the "glucose" of the Pharmacopoeia is corn syrup, a mixture of dextrin, maltose, dextrose and water and has quite different properties from refined crystalline dextrose.

As defined by the U. S. Food and Drug Administration in *Service and Regulatory Announcements*, 4th Revision, 1933: "Dextrose is the product chiefly made by the hydrolysis of starch or a starch containing substance, followed by processes of refining and crystallization. (When derived from cornstarch, dextrose is known commercially as refined corn sugar.) Hydrated dextrose contains not less than 90 per cent of dextrose and not more than 10 per cent of moisture, including water of crystallization. Anhydrous dextrose contains not less than 99.5 per cent dextrose and not more than 0.5 per cent of moisture."

Anhydrous dextrose is prepared by recrystallization of the hydrated dextrose, ground very fine and heated to 60°C. to remove the molecule of water of crystallization. This is the form of dextrose used for intravenous injections and in various pharmaceutical and medicinal preparations. Manufacturing details have been fully described by Krno,¹⁰ Cathcart,⁴ and Arnold.¹

The present annual production is increasing steadily year after year. Refined dextrose makes up only about 25 per cent of the total annual corn sugar

production of one billion pounds. The balance consists of confectioners' glucose, syrups, etc. The total sugar consumption per capita in our country is about 115 lb. Of this, 16 lb. is eaten as candy.

In truth, this is a staggering amount of sweets, when it is considered that in 1800 the per capita consumption was only about 10 lb. On the other hand, sugar is one of our most available and convenient and inexpensive sources of body energy, and scientific evidence has still to be adduced to show that any harmful effects result from the ingestion of large amounts of it.

The corn crop for 1938 is estimated by the U. S. Department of Agriculture at 2,260,000,000 bushels—a truly stupendous raw material source for dextrose manufacture. At the prevailing low cost of corn, dextrose can be manufactured to sell at considerably below the market price of sucrose. For these and other reasons we shall probably see in the future increased use of dextrose as food.

As yet dextrose makes up a relatively small part of the nation's sugar bowl; yet, with its increasing use as pure sugar and in foods and beverages, we may well inquire, both as public health officers and as consumers, into the nutritional and sanitary status of this food.

PROPERTIES OF DEXTROSE

Commercial dextrose is a fine, white crystalline product containing from 7 to 9 per cent water. Our analysis shows the following composition.

	<i>Regular dextrose hydrate per cent</i>	<i>Recrystallized dextrose hydrate per cent</i>
Moisture	7.75	8.00
Dextrose	91.40	91.80
Purity of dextrose solids	99.80	99.90
Ash	0.05	0.009
Iron	0.0001	0.0002
Chlorine	0.016	0.002
Sulfates (SO ₄)	0.008	0.008
Silica (SiO ₂)	0.0035	0.005
Calcium	0.0022	0.002

The high purity of dextrose is shown by this analysis. It corresponds to the purity of good quality cane or beet sugar. Because of the water of hydration in the dextrose molecule it is necessary to use 109.4 lb. of dextrose in order to supply the same sugar solids that are present in 100 lb. of sucrose. Dextrose is approximately 75 per cent as sweet as sucrose. According to one's point of view this lower degree of sweetness may be considered either an advantage or a disadvantage. The solubility of dextrose in water is somewhat less than that of sucrose, hence because of sugar crystal formation, jellies and preserves cannot be manufactured using only dextrose. Our laboratory⁶ as well as Van Arsdale and Eddy²³ have found that mixtures of dextrose and sucrose containing from 20 to 50 per cent dextrose are very satisfactory in the manufacture of most fruit products such as jams, preserves, jellies, and canned fruits. As shown by Berkeley and Hortley² dextrose solutions show considerably higher osmotic pressures than sucrose. That dextrose syrups do actually possess somewhat greater bactericidal action against yeast and bacteria than sucrose, is experimentally shown by Morrison.¹³

In crushed fruits and fountain syrups dextrose is now very extensively used in proportions of from 25 to 50 per cent of the total sugar.^{8, 17} The carbonated beverage industry uses up to 40 per cent of total sugars as dextrose in its syrup bases. This sugar, according to Buchanan,³ gives a more suitable body, reduces sweetness, and improves flavor. When dextrose replaces sucrose in carbonated beverages the added acid can be reduced by 10 to 15 per cent.

The Institute of American Meat Packers have found that reducing sugar (dextrose) prevents fading due to oxidation of the hemoglobin, and thus holds the red color. It is particularly efficacious in wet pickled meats, sau-

sages, and even in fresh and canned meats.

The extensive use of dextrose and various corn syrups in the baking industry hardly need be mentioned. As shown by Morison and Gerber,¹² dextrose and sucrose are interchangeable in yeast bread doughs and the loaf volume, flavor and sweetness are identical. The usual sugar percentage in bread formulae is now about 6.

Both dextrose and corn syrups are used in immense quantities in the manufacture of candies, sweet chocolate, marshmallows, and other confections. In dairy products, ice creams and sherbets may contain from 15 to 25 per cent of the total sugar as dextrose according to Tracy²²; and in condensed milks the use of dextrose is advantageous as reported by Hunziker.⁹

Results in our own laboratory^{6, 8} show that from 20 to 50 per cent dextrose can be used successfully in sweet pickles, relishes, and similar products. Other investigators have shown the feasibility of using dextrose in frozen or "cold pack" fruits in candied and glacéd fruits, in Maraschino cherries, licorice, wines, in fermented sauerkraut, dill pickles and olives. Considerable quantities are also used in pharmaceutical and medicinal products.

I need not enumerate more ways where dextrose can and is being used in foods and beverages. The fact remains that we are buying and eating large quantities of dextrose every day whether we know it or not. I think the industry is rather desirous that the public be informed about dextrose if one can believe the extensive advertising slogans seen everywhere in this country and in England.

LEGAL AND PUBLIC HEALTH ASPECTS

In 1930 the Secretary of Agriculture, Arthur M. Hyde, ruled that refined dextrose, as well as sucrose, could be used in the manufacture of food prod-

ucts without label declaration. Hence, the extensive use of dextrose in foods dates back only 8 years. While a few states still require the labelling of some manufactured foods containing dextrose, the wisdom of retaining such regulations seems questionable. Certainly no fraud is perpetrated and no nutritional or public health aspects are concerned. Dextrose and sucrose have practically equivalent purity and nutritive values. The former contains fewer microorganisms. Since corn is one of our staple agricultural crops and a surplus is often produced, it would seem to be in the public interest to extend rather than to restrict, the use of refined dextrose. In fact, it is doubtful that any state fully enforces its local regulations relative to the labelling of dextrose in all the products in which it is used—that is, candy, bread, ice cream, jams, preserves, pickles, condensed milk, meats, soda fountain syrups, canned foods, and carbonated beverages. In fact, there is no sound public health argument for doing so. The presence in a state of a competing sugar industry is not a sound reason for legislating against dextrose.

Nutritionally, dextrose and sucrose are equivalent. Excellent reviews on the physiology and biochemistry of sugars have been recently published by The Council on Foods of the American Medical Association,⁵ and by Pierce¹⁸ in the *Journal of Nutrition*. Dextrose is the normal sugar of the blood. When eaten, it is quickly absorbed as such and circulates unchanged in the blood stream. The work of Roberts¹⁹ indicates that dextrose is absorbed from the intestinal tract more rapidly than sucrose, though Murlin and Manly¹⁴ show that the absorption rates for the first 2 hours after ingestion are not significantly different. The studies of Schultz and Blish²⁰ on children showed that dextrose was the most efficient of the sugars studied for the alleviation

of the accumulation of lactic acid due to exercise. That the nature of the carbohydrate in the diet has relatively little effect on calcium and phosphorus retention in the body was reported by Speirs and Sherman.²¹ One of the more recent clinical (and possibly practical) uses for dextrose is suggested by the work of Haggard and Greenberg of Yale University.⁷ They found that the toxic effect of alcohol is influenced in inverse proportion to the amount of sugar in the blood. Thus, sugar will greatly decrease the pharmacological effect of alcohol, i.e., make it less intoxicating.

An excellent text called, "Dextrose Therapy in Everyday Practice" by E. Martin¹¹ reviews more than 2,000 articles on experimental and clinical studies on dextrose.

It is not the purpose of this short paper to show superiority of dextrose over other forms of carbohydrates, but merely to point out that a great mass of physiological evidence exists which proves that dextrose is certainly not inferior to other sugars in a nutritional sense. With refined carbohydrates now forming about 25 per cent of man's caloric intake we should take stock of refined dextrose, which within a very few years, has become a major component of so many of our everyday prepared foods.

Relative to the use of dextrose from a sanitary point of view, essentially no problems exist. The sugar is pure, clean, practically free from bacteria or other microorganisms, and contains no

toxic contaminants such as heavy metals, fluorine, selenium or arsenic.

It remains only to state that a careful review of the physical, chemical, and physiological properties of dextrose, its present use in the food industries, and its hygienic aspects lead to the conclusion that refined dextrose as marketed today in the United States presents no important public health problems.

Preparation of Scarlet Fever Toxin*

MARY E. EVANS AND RUSSELL Y. GOTTSCHALL, PH.D.

Bacteriologist, and Senior Bacteriologist, State Department of Health, Lansing, Mich.

THE publication by Rane and Wyman¹ of a flocculation test for scarlet fever toxin was of great potential value in the development and study of better scarlet fever antigens, just as Ramon's discovery of the flocculation test for diphtheria toxin facilitated the study of diphtheria toxin and toxoid. This paper is concerned with verification of this important work of Rane and Wyman, and with the use of the method, to guide the production of scarlet fever toxin of higher flocculating values. The flocculating test is especially advantageous in the study of scarlet fever toxins, since titration by the usual skin test method is time consuming and relatively inaccurate, unless many rabbits² or Dick positive human volunteers are used.

Until recently the production of potent scarlet fever toxin on beef or veal infusion broth or semi-synthetic media was none too successful, toxins with skin test doses of 200,000 to 300,000 per milliliter being considered very strong. O'Meara,³ however, was successful in producing toxins containing 1,000,000 to 5,000,000 skin test doses per ml. with a "straight line" digest of horse muscle containing 1 per cent peptone. One of the disadvantages of

this method is the use of horse muscle which makes the toxin unsuitable for human immunization.

The crude toxins prepared by Rane and Wyman¹ in their study of the flocculation reaction averaged 2-3 L_t units and 120,000 to 180,000 S.T.D. per ml. and were concentrated to obtain rapidly flocculating toxins. By modification of their methods we have, during the past year, produced crude toxins with L_t values as high as 26 units and with skin test doses as high as 1,000,000. Concentration of these toxins is therefore unnecessary and the L_t determinations are now made with the same ease and accuracy as in testing diphtheria toxin by the flocculation method.

Because of the potency of these toxins the methods of preparation are given in detail.

INFUSION MEDIUM

This medium is prepared by infusing 1 lb. of ground fat-free veal in 1 l. of distilled water for 12 to 18 hrs. at 5°C. The mixture is then boiled for 15 to 20 min., the meat strained out and pressed, and the liquid filtered through paper. Two per cent proteose peptone is added and the pH adjusted to 7.6 to 7.8 with sodium hydroxide. The broth is finally filtered through absorbent cotton and dispensed in 2 l. amounts in 3 l. Erlenmeyer flasks. It is sterilized by autoclaving at 120°C. for 20 min.

* Read before the Laboratory Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 28, 1938.

INFUSION FREE MEDIUM

The semi-synthetic medium is a modification of the Wadsworth and Wheeler formula⁴ for the preparation of diphtheria toxin and has the following composition:

Potassium phosphate C.P. K_2HPO_4	1.0 g.
Sodium phosphate C.P. $NaH_2PO_4 \cdot H_2O$	1.0 g.
Magnesium sulphate C.P. $MgSO_4 \cdot 7H_2O$	0.2 g.
Calcium chloride C.P. $CaCl_2$ anh.	0.1 g.
Peptone, Proteose, Difco	20.0 g.
Ammonium lactate, C.P.	4.5 g.
Succinic acid	2.0 g.
Distilled water	1,000.0 ml.

The peptone is dissolved in approximately 700 ml. of distilled water. Each of the salts is dissolved separately in a small quantity of water and added to the peptone solution in the order given. The volume is brought to exactly 1,000 ml., the pH adjusted to 8.0 with sodium hydroxide and the medium boiled for 3 to 5 min. It is filtered through paper, dispensed in 2 l. amounts in 3 l. Erlenmeyer flasks, and autoclaved at 120°C. for 20 min.

OTHER MEDIA

The dried complete medium described by Bunney and Thomas⁵ for production of diphtheria toxin can also be used for the preparation of scarlet fever toxin. We have obtained toxins containing 400,000 S.T.D. and 9 L_t units with this medium.

Although toxins have been prepared with the horse muscle digest medium described by O'Meara³ which contained 1,000,000 S.T.D. per ml., flocculation of these toxins with our antitoxins has thus far been unsuccessful.

CULTURE

Toxin is prepared from the Dochez No. 5 strain of hemolytic streptococcus. The culture is retained on blood agar, virulence being maintained by weekly passage through mice. Before a lot of toxin is prepared the strain is acclimated to that specific lot of broth by

several successive transfers in 5" by $\frac{5}{8}$ " culture tubes containing 6 ml. of the medium enriched by the addition of 0.1 per cent dextrose.

TOXIN PRODUCTION

The method of inoculation, incubation, adjusting of pH, and addition of 50 per cent dextrose solution for the infusion medium is similar to that described by Rane and Wyman.¹ Because growth is slower on the semi-synthetic medium the cultures are kept at 37.5°C. for the first 18 hrs. but otherwise the method is identical with that used for the infusion broth.

After the required quantity of dextrose has been added and purity tests are made, sufficient phenol is added to the pure cultures to make a concentration of 0.5 per cent. The toxin is then filtered and tested for potency.

TITRATION OF TOXIN

The S.T.D. of the toxins is determined by intradermal injection into rabbits, every 5th or 6th lot being tested on human volunteers.

In the flocculation test rapidly flocculating accurately standardized antitoxins containing 150 to 200 units are used, antitoxin being measured with the Trevan-O'Brien syringe. The technic is similar to that described by Rane and Wyman.¹ The S.T.D. and L_t value of the last 18 lots of toxin prepared within the past 18 months are given in Table I.

The speed of flocculation of the crude toxins varies with the L_t value, toxin No. 210 containing 20 units flocculates in 20 minutes at 45°C. and No. 206 containing 4 L_t units requires 10 to 12 hours at this temperature.

With the stronger toxins flocculation may appear in several tubes simultaneously. It is necessary to dilute these toxins to obtain accurate readings. This phenomenon was also observed by Rane and Wyman in the flocculation of their concentrated toxins.

TABLE I

A Comparison of the L_t Value and the S.T.D. of 18 Lots of Crude Scarlet Fever Toxin

Lot No.	Broth	S.T.D. per ml.	L_t per ml.
204	Infusion	500,000	6
205 A	"	1,000,000 *	26
B	"	1,000,000	16
206	"	1,000,000 *	4
207 B	"	500,000	14
208	Complete dried medium	400,000	9
209	Infusion	500,000	9
210	"	500,000	21
211	"	<300,000 *	8
212	"	1,000,000	7
213	"	1,000,000	14
214	"	"	24
215	"	1,000,000	20
216	"	300,000 *	8
217	"	1,000,000	4
218	Semi-synthetic	1,000,000	19
219	"	"	7
220	"	500,000 *	20

* Checked on human volunteers

DISCUSSION

The results in Table I indicate that there is very little correlation between the skin test dose and the L_t value of our crude toxins, particularly when prepared from the infusion medium. Toxins No. 205 A and 206, for example, had a skin test dose of 1,000,000 but the former toxin had an L_t value of 26 and the latter an L_t value of only 4. That these were the correct determinations and not nonspecific zonal flocculation values was verified by testing these toxins over a range of 2 to 60 units. The results with semi-synthetic media indicate that, with this medium, there may be a closer relationship between the S.T.D. and the L_t value. Rane and Wyman,¹ on the other hand, found a definite L_t -S.T.D. ratio, one L_t unit being equivalent to approximately 60,000 S.T.D. of toxin. Their results were based upon flocculation tests on toxins purified by ammonium sulphate but the concentrates were prepared from both infusion and infusion-free media.

Several toxins prepared from the horse muscle digest medium described by O'Meara³ which were particularly

strong when the toxicity was measured by the skin test reaction have, in our hands, been found entirely devoid of flocculating ability in the crude state. The author of this method also found these toxins to be lower in flocculating substance than toxins prepared by other procedures.

The L_t value from one flask to the next with a given lot of toxin prepared at the same time and in the same manner varies considerably. The approximate titer of 10 cultures comprising one lot of toxin is given in Table II.

TABLE II

The Variation in L_t value of 10 Cultures Comprising a Single Lot of Scarlet Fever Toxin

Flask No.	L_t per ml.
1	14
2	22
3	18
4	<10
5	<10
6	<10
7	18
8	<10
9	22
10	<10

The L_t values of the individual cultures of this lot vary from less than 10 to 22 units, and each lot of toxin given in Table I was therefore pooled from 10 to 12 individual cultures.

We are continuing this study with the view of finding a simpler method of preparing high potency toxin with the Dochez No. 5 strain. The recent report of Rane and Wyman⁶ describing the production of toxin containing 10 to 80 L_t units from the No. 594 strain of hemolytic streptococcus may be very important if this strain is found to have as wide a valency as the Dochez No. 5 strain.

It will remain to be shown whether there is any correlation between the L_t value and the antigenicity of scarlet fever toxin.

SUMMARY

The report of Rane and Wyman

showing that scarlet fever streptococcus toxin flocculates with antitoxin has been confirmed.

Methods for the preparation of crude scarlet fever toxin with hemolytic streptococcus, strain Dochez No. 5 and having L_t values of 4 to 26 units and skin test doses as high as 1,000,000 which flocculate directly are described.

NOTE: We wish to express our gratitude to W. E. Bunney for his valuable suggestions and support throughout this study and to J. T. Tripp for testing our toxins on human volunteers.

Results of Venereal Disease Control in Canada*

GORDON BATES, M.D.

General Director, Health League of Canada, Toronto, Ont., Canada

THE venereal disease control movement in Canada began during the Great War. Previous to the war factors had begun to operate which were calculated ultimately to call the problem to public attention. The most potent of these was the discovery of the Wassermann reaction. The gradual application of this test, especially in institutions, revealed that syphilis was far more prevalent than anyone had suspected. One recalls that in pre-Wassermann days the relationship between such conditions as aortic aneurysm, general paralysis of the insane, and tabes dorsalis with syphilis were not considered to be invariable. With the development of the Wassermann technic the relationship was confirmed but in addition positive diagnosis was established in thousands of other cases and the discovery of additional thousands of cases of entirely unsuspected disease created a growing appreciation of the fact that in syphilis we had a problem of major public health importance. There was also a growing appreciation of the seriousness of gonorrhea as a major cause of disability. In 1913, a group of British physicians, headed by Sir William Osler, Regius Professor of Medicine at Oxford,

and Sir Clifford Albutt, Regius Professor at Cambridge, wrote a letter to a morning newspaper in London, England, calling attention to the need for governmental action. The result was the Sydenham Royal Commission appointed by the Asquith Government which sat for 3 years and brought in a startling report in April, 1916.

Evidence was presented to this Royal Commission to the effect that 10 per cent of persons living in cities in Great Britain were infected with syphilis, that there were 100,000 fresh infections of this disease a year, and that gonorrhea was much more prevalent than was syphilis. The two diseases were responsible for an enormous amount of disability, and the beds of hospitals, insane asylums, and institutions for the blind and defective were filled by thousands of their victims. The rôle of syphilis as a major cause of death was recognized.

While interest in the subject was rapidly growing war broke out. During previous wars scientific knowledge had not progressed enough to suggest particularly strenuous methods of control, but in the Great War venereal diseases were from the beginning treated as a serious problem. The routine Wassermann was not instituted as a means of keeping syphilitics out of the army, and many syphilitics became soldiers. Regular inspection resulted in the detection of many new

* Read before the Health Officers Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 26, 1938.

cases of gonorrhea and syphilis in enlisted men. All cases when discovered were promptly isolated and treated. Venereal disease hospitals were erected, and in every army the segregation of thousands of venereal cases provided visible evidence that the prevalence of venereal disease seriously interfered with army efficiency.

It was also realized that all of these cases originated in the civil population and in order to prevent fresh infection methods were evolved to trace and treat civil cases. The use of the so-called social case sheet in connection with investigating the origin of infection in soldiers made it possible in the Province of Ontario to arrive at an estimate of the prevalence of the two diseases.

In 1916, a deputation from Toronto to the Canadian Conservation Commission submitted that 12.8 per cent of patients in the Toronto General Hospital showed a positive Wassermann reaction. The following year, 1917, routine Wassermann reactions in Montreal General Hospital showed that 26 per cent of the patients in that hospital were infected. The seriousness of the situation both in military and civil life resulted in the appointment of a Royal Commission on Venereal Diseases in Ontario, and in 1918 the Ontario Legislature passed the Ontario Act for the Prevention of Venereal Diseases. This legislation provided a standard type of legislation upon which legislation in most other provinces was based.

There has been much discussion of the results of the Scandinavian program and of Scandinavian legislation. Typical Canadian legislation included most of the characteristic features of the Scandinavian law. Legislation of nearly all of the provinces included a provision whereby the physician was required to report cases of venereal disease to the local health authority by number. Where the patient neglected treatment

the physician was instructed to report the case by name, whereupon the medical officer of health was empowered to give such direction for the treatment of the patient and, if necessary, for his detention, isolation, and prevention of infection from him, as he deemed necessary and as authorized by regulations which were subsequently drawn up. Persons under arrest or in custody could be examined by the medical officer of health and treatment carried out under his direction. Another important section of the typical venereal disease legislation provides that where the medical officer of health is credibly informed that any individual is infected with venereal disease and may infect others, steps may be taken to ascertain the condition of such person and institute treatment if necessary.

Hospitals are required to make effective provision for the examination and treatment of venereal disease. Persons other than legally qualified medical practitioners are forbidden to treat venereal disease. The advertising of venereal disease remedies is forbidden.

Under various venereal disease acts, of which the above provisions are typical, most of the Canadian provinces undertook to place venereal disease in a category similar to that in which other communicable diseases are placed. Venereal disease literature of a standard character was printed in most of the provinces in order that the personal education of the venereal disease patient might not be neglected. It was felt that the Canadian legislation was at least as adequate and far reaching as any other for the control of these sinister maladies.

Legislation, however, was not sufficient to control venereal diseases. It was necessary to provide clinics for the thousands of patients who were likely to apply for diagnosis and treatment, lacking the necessary funds to pay for it. In addition we had scarcely emerged

from the stage where it was considered highly improper to use the words gonorrhea or syphilis in public. Obviously people in general knew little or nothing about the signs or symptoms or seriousness of venereal diseases. Even if infected they were unlikely to realize the importance of prompt and efficient treatment. An educational campaign was necessary.

Partly because public opinion was aroused and to a degree because of the interest of a far-sighted member of the Dominion Cabinet, the Honourable N. W. Rowell, first Minister of Health for Canada and now Chief Justice of the Supreme Court of Ontario, a conference was called in Ottawa, May, 1919, for the discussion of a national venereal disease control program. All Provincial Chief Officers of Health, as well as representatives of many national organizations, were present.

There had been in the United States a fine wartime venereal disease control program. The Chamberlain-Kahn Bill had provided what seemed to be the beginning of a fine civil program. Secretary of War Baker kindly sent two army officers to the Canadian conference to describe the activities commencing in the United States—and largely because of the fact that the Chamberlain-Kahn Bill had provided for state subsidy in this field, at the Canadian conference the sum of \$200,000 annually was set aside out of Dominion funds for this purpose:

1. The maintenance of a Division of Venereal Diseases at Ottawa
2. The partial subsidy of a voluntary association to undertake public education
3. The making of grants to the various provinces in proportion to their population and on condition that each province spend in an amount equal to their Dominion grant.

This Dominion-wide scheme came into existence simultaneously with the

establishment of the Dominion Department of Health in 1920.

The subsidizing of a voluntary organization was an extremely important part of the plan. It was felt that in the absence of organized public opinion a change in the federal government might easily result in a Dominion administration unfriendly to Dominion participation in the scheme or that failure to keep the public fully informed as to the need for the continued appropriation of public funds for venereal disease control might result in an apathy which would destroy the scheme with equal effectiveness. Therefore it was resolved to make no mistake about insuring the continuance of organized public education. This was a definite part of the scheme which resulted in the machinery of the plan remaining intact for 11 years. The Canadian scheme came into effect to a degree as the result of the example set by the United States in their fine wartime plan and by the possibilities which seemed to be opened up by the Chamberlain-Kahn Bill. It preceded the present splendid coördinated plan in the United States by 15 years.

The expenditure on venereal disease control in Canada, with a population of 10,000,000, amounted to \$400,000 annually by the Dominion and the provinces alone for a number of years. The amount of Dominion grants for venereal disease control was later reduced and, in 1931, as the depression became acute and partly as a result of the depression, the Dominion grants were discontinued altogether. Later the grant to the voluntary association, now known as the Health League of Canada, an organization with a broad program of health education, including venereal disease, was restored in part and a grant of \$50,000 was made this year (1938) by the Dominion to pay for drugs used by the provinces in the treatment of venereal disease. It is

hoped that this action by the Dominion Government indicates the renewal of Dominion leadership in this field.

The assumption of Dominion leadership in Canada, in 1920, in the venereal disease control program, had immediate effects. The provinces stimulated by the financial support of the Dominion Government immediately commenced to organize special departments under specialist officers. Clinics rapidly sprung into existence in all of the provinces so that, while previous to the development of the Dominion-wide scheme there were a few scattered clinics and no co-ordinated action, soon all provinces were coöperating. Shortly there were a hundred clinics in operation and the number of treatments increased year by year. The machinery of clinic management including social follow-up methods progressively improved.

The voluntary association which from the beginning was an integral part of the scheme was for the first year of its existence called the National Council for Combating Venereal Disease. This organization took the lead in the necessary educational program. Chief officers of health for the province became executive members of the association and with prominent citizens, lay and medical, assisted in the public spreading of information on all phases of the subject. The utilization of a moving picture, "The End of the Road," a wartime film developed through the coöperation of the American Social Hygiene Association and the Young Women's Christian Association, shown to hundreds of thousands, was instrumental in attracting thousands of patients to the newly established clinics.

An arrangement with the distributing company whereby the words, "venereal disease," must be used in all advertising copy in all parts of Canada soon accustomed Canadian newspapers to the frank discussion of a subject which had previously been studiously avoided, in

both news and editorial columns. As a result of this early arrangement there has been for many years now little tendency on the part of Canadian newspapers to avoid the frank discussion of the Venereal Disease problem. In the second or third year of the scheme the voluntary association, by this time known as the Canadian Social Hygiene Council, was fortunate in procuring the services of Mrs. Emmeline Pankhurst, the famous leader of the Suffrage Movement in England. Mrs. Pankhurst, a great and sincere woman, for several years a member of the staff of the Canadian Social Hygiene Council, made a wonderful contribution to the cause. Campaigns were organized in which Dr. J. J. Heagerty, at that time Director of the Venereal Disease Division at Ottawa, Mrs. Pankhurst, the General Secretary of the voluntary association, and provincial health officers addressed great meetings in various parts of Canada. Campaigns instituted throughout the Dominion using these methods at this time were extraordinarily successful in enlisting public sympathy and support.

An unusual type of campaign was instituted in the Province of Quebec. In this province it was decided to depend almost entirely on a voluntary scheme. No very definite legislation was put on the Statute Books. Instead Dr. A. H. Desloges, Director of the Division of Venereal Diseases, instituted a unique method of obtaining public coöperation and developing his educational campaign. In the Province of Quebec we have a population composed largely of French-Canadians of the Roman Catholic faith. A direct appeal was made to the Church for co-operation in a great campaign of enlightenment. The response was prompt and striking. Meetings were arranged in all parts of the province presided over by priests, bishops, and even archbishops. Competent medical men lec-

tured, films were shown, and literature was distributed.

Organization of centers for free treatment was developed and trained physicians administered treatment.

I refer to this coöperation of the Roman Catholic Church in Quebec because I believe it to be unique in the history of organized educational methods for the control of this particular type of disease. Meanwhile work was carried on throughout the other provinces of Canada, all of which coöperated in the coördinated scheme under Dominion leadership.

The Canadian scheme had 3 essential factors:

1. Federal leadership resulting in coöperative action among the Dominion, the provinces, and municipalities.

2. A strong voluntary association to keep up a continuous educational program. This educational program not only educated the individual to seek treatment if infected, but it induced the tax payer to endorse the expenditure of public funds on venereal disease control.

3. Adequate legislation in all but one province.

This plan was continuous between 1920 and 1931. The withdrawal of federal grants in 1931 might well have been calculated to wreck the entire Canadian scheme. However, the passage of years had meant the stabilization of provincial efforts and the result was that although the provinces were compelled to carry on by themselves, and although in some cases budgets were reduced, still venereal disease control work continued throughout the whole of Canada.

The voluntary association lacked government subsidy in the lean period, yet managed to develop the moving picture, "Damaged Lives," which since 1933 has been shown in practically all English speaking countries as well as in some others. This year this picture is reported as showing for the first time in South Africa, Singapore and the

Straits Settlements, the Philippines, India, and China. As a result of the Canadian scheme we have records of the treatment of several hundred thousands in clinics, and although the reporting by physicians has been inadequate, unquestionably many other thousands have sought treatment from private physicians who otherwise would not have done so.

It is extremely difficult to appraise the results of a venereal disease control plan as statistics in this field are likely to be misleading. Surveys have been done by the Canadian Social Hygiene Council, now the Health League of Canada, in 3 cities—Toronto, Winnipeg, and Ottawa. The first surveys showed a lower incidence in Toronto and in Winnipeg than in 17 American cities surveyed at about the same time, in 1929. Subsequent surveys have brought out some extremely interesting results. The last two surveys done in 1937 were in Toronto and Ottawa. These surveys undertaken by a joint Committee of the Health League of Canada and the Academy of Medicine were carried on by writing circular letters to all practising physicians and to all clinics and all institutions in an attempt to ascertain the number of cases of gonorrhea and syphilis under treatment at one time. The Toronto survey and the Ottawa survey showed approximately the same percentage of venereal disease in the population. For example, the rate of incidence of the two diseases in Ottawa was 9.95 per 1,000 population as compared with 9.56 per 1,000 in Toronto. The total number of cases of syphilis and gonorrhea reported through the survey in Toronto, in May, 1937, showed 6,188 in an estimated population of 645,462. There were 3,639 cases of syphilis and 2,549 of gonorrhea, rates of 5.6 and 3.94 respectively per 1,000 population.

The first survey done in Toronto was in 1929 and since that time the actual

number of cases under treatment had increased, but there was a remarkable change in the type of case under treatment. In the 1929 survey there were 909 cases of "early" syphilis under treatment. In 1937 this number had been more than cut in half. There were 433 cases under treatment.

In 1929 there were 2,259 cases of "late" syphilis under treatment. In the 1937 survey this number had increased to 3,266. In other words there was an actual decrease in "early" cases under treatment of over 50 per cent, and an increase in the number of "late" cases under treatment of considerably over 50 per cent. It is a little difficult to understand what such statistics mean unless one considers them side by side with the records of the results of routine Wassermanns in institutions. Table I gives the record of syphilis in Toronto General Hospital, 1916-1935.

TABLE I

*Routine Wassermanns Positive in
Toronto General Hospital*

	<i>Per cent</i>		<i>Per cent</i>
1916.....	10.4	1926.....	4.5
1917.....	9.95	1927.....	3.8
1918.....	5.9	1928.....	3.5
1919.....	8.8	1929.....	3.2
1920.....	9.0	1930.....	3.4
1921.....	6.3	1931.....	2.7
1922.....	6.0	1932.....	2.5
1923.....	6.2	1933.....	2.5
1924.....	5.6	1934.....	1.7
1925.....	5.8	1935.....	1.5

In the same time in the nearby hospital for Sick Children the percentage of routine Wassermann tests which were positive fell from 5 per cent to less than 1 per cent. In St. Michael's Hospital, Toronto, the percentage of positives over the last 5 years has averaged 2.03 per cent. In Kingston General Hospital in Eastern Ontario the latest report is 1.3 per cent.

Considering these statistics with the statistics concerning the number of

early and late cases under treatment, one is forced to the conclusion that in the period under review there has been a marked fall in early syphilis. In addition, hospital statistics prove that there is much less late syphilis. In spite of this a greater number of cases of late syphilis are under treatment. One must conclude that the detection of late syphilis, particularly by means of the routine Wassermann reaction, has improved.

Dr. Parran¹ in discussing a paper by Dr. Einar Rietz, Commission of Health in Stockholm, Sweden, states that in the Rigs Hospital in Copenhagen, the Dean of the Medical Faculty and Professor of Obstetrics, said that among nearly 2,000 deliveries over 3 years the number of cases of syphilis as shown by routine Wassermann tests and careful histories, varies from 30 to 35 per year. A recent survey in the Lying-in Hospital of Toronto General Hospital showed that in 1,000 successive pregnancies the Wassermann was positive in but 3 cases. Apparently the Copenhagen rate was 1.7, the Toronto rate 0.3.

After every great war in history the late end results of syphilis have become more evident. The Canadian Department of Pensions and National Health stated that shortly after the war two reliable sources of information, one European and the other American, forecast that 2.5 to 4.5 per cent of syphilitics would have developed tabes or general paralysis of the insane in 20 years from the date of initial infection but that as a matter of fact only 0.5 per cent of known cases of syphilis in the Canadian Expeditionary Force have developed either of these serious nervous system sequelae. Similarly there has been a marked decrease in congenital syphilis and in other end results such as heart disease of syphilitic origin. I can find no evidence whatever that there has been any decrease in gonorrhea.

There are many other additional evidences of decrease in syphilis. University medical schools report the greatest difficulty in finding primary cases of syphilis to demonstrate to students. Dr. Harold Orr of the Social Hygiene Division of the Department of Public Health of the Province of Alberta, reports that the incidence of syphilis in Alberta jails has been reduced from 16 per cent in 1920 to 4 per cent in 1937. He states that in a clinic in Edmonton during the past year there has only been one primary sore and not a single case of secondary syphilis.

I believe that I am correct in saying that up to 1931-1932 in spite of deficiencies which might be demonstrated Canada had a venereal disease control scheme which was second to none in efficiency. The withdrawal of Dominion grants in 1932 had a serious effect on the venereal disease control scheme in Canada. These grants by the Dominion Government to the provinces were withdrawn in the face of recommendations made by the groups of specialist clinicians representing all of the provinces, called in conference in different parts of Canada. A review of the recommendations is interesting in that they summarize a number of the essentials for venereal disease control in the future.

The Canadian Conferences of Clinicians (specialists in the venereal disease field) recommended as follows:

1. That intensive propaganda and education in this field be continued and that the value of concerted action throughout the Dominion be emphasized.

2. That more attention be paid to the personal education of venereal disease patients in order to insure continuous attendance.

3. That clinics be kept open from 8 a.m. to 12 p.m. in order to provide for early treatment (within 8 hours after exposure).

4. That methods be evolved to insure the continuous treatment of transient patients by providing them with a form upon which

records of treatment given them may be inscribed by successive clinics or physicians.

5. That the problem involved in the treatment of indigents in rural areas be dealt with by provincial departments of health.

6. That provision for fever treatment of cases of general paralysis of the insane be provided in all large general hospitals.

7. That in view of the fact that many physicians still give voluntary service in venereal disease clinics provision be made for the proper remuneration of all physicians attached to venereal disease clinics.

8. That all venereal disease clinics be equipped with darkfield apparatus for the diagnosis of primary syphilis and that all hospitals with venereal disease clinics procure such apparatus.

9. That in view of the ever increasing number of patients attending genitourinary clinics showing the effects of mal-treatment of gonorrhea, teaching of medical schools of this subject be improved.

10. That similar facilities for the improved teaching of syphilis be established and that special reference be made to darkfield examination.

11. That the inclusion of specific questions on the subject of gonorrhea and syphilis in the annual examinations in medicine and surgery would be a distinct contribution in the campaign against venereal disease.

12. That medical associations be asked to include papers on venereal disease in their programs for meetings.

13. That meetings of specialist clinicians be held once a year possibly in connection with the meetings of provincial medical associations at which the latest methods and information on the subject might be discussed.

14. That a specific publication for the instruction of physicians in all phases of the question of venereal disease be developed.

These are but some of the recommendations which were brought forward as essential to the further development of the Canadian venereal disease control scheme and in order that these recommendations might be made effective it was urged that the contribution of the Dominion Government to the plan be increased.

I am able to report that there has been a renewal of interest, that this year for the first time since 1932 the Dominion Government has made a contribution to the scheme in the form of

payment for drugs used in treatment in clinics. This amounts to \$50,000.

A committee of the Health League of Canada has completed a book of instruction for the guidance of the physician which will be issued generally to physicians by the Dominion Department of Health. Plans for the carrying on of treatment in rural areas have been improved by the provision in some provinces of funds for the payment for treatment of indigents by private physicians, and necessary drugs are provided free. The provision of facilities for taking specimens for darkfield examination in outlying districts and transportation of such specimens to a central laboratory in a convenient mailing packet has facilities for diagnosis of early syphilis in remote areas.

Many of the improvements in the Canadian scheme still remain to be achieved. We have had a fine coöperative effort which has accomplished a great deal, yet we must acknowledge that during the last few years the progress which was characteristic of the early years of the movement has not been made. Essential and specific improvements in the scheme are suggested by the recommendations of physicians especially interested in the ultimate success of the venereal disease program, a few of which are described in this paper. Venereal diseases are controllable although as a problem they are more difficult to deal with than are most of the other major problems in public health.

Both in the United States and in Canada these dangerous maladies are a national problem, common to all states and all provinces. As such they deserve the attention of federal authorities. I believe that we have proved in Canada that under Dominion leadership a great deal can be accomplished. With the fine coöperative scheme you have developed in the United States you are achieving

similar results. I suggest that *only* under central leadership can such a problem be effectively dealt with.

Syphilis, toward the end of the Great War, was characterized by Sir William Osler as the greatest single cause of death among the infections. This meant that he considered that syphilis as a killer outranked tuberculosis, cancer, and pneumonia. As a matter of fact syphilis for a time in England was characterized as the "great killer." Syphilis in Canada is no longer the great killer. Hospital statistics prove that. Yet, syphilis we still have with us in spite of a yearly reduction in the incidence of primary cases, and the fact that in 1936 392 fresh cases of general paralysis of the insane were admitted to Canadian hospitals for the mentally ill, is proof that syphilis, although many of its end results have been almost eliminated, still does a great deal of damage. As for gonorrhea, serious though the disease is, there is little evidence that its incidence has been reduced either in Canada or elsewhere.

I believe that the future holds great possibilities not particularly because the seriousness of venereal diseases alone is recognized but because of the fact that it is becoming more generally recognized that most illness is preventable, that there is no logic in filling expensive hospital beds with people who should not become ill and cemeteries with the bodies of those who should still live. As nations recognize the fact that their greatest asset is long-lived healthy and efficient men and women, and as we build machinery for the preservation of health on a national scale these most tragic of maladies will disappear with the rest of the unnecessary germ-borne maladies which have destroyed the health and shortened the lives of humans in the past.

Industrial Hygiene Program in a State Health Department*

CARL A. NAU, M.D.

Director, Division of Industrial Hygiene, Texas State Department of Health, Austin, Tex.

ANY program of industrial hygiene will depend upon two major factors: the definition, and the objectives of industrial hygiene.

Webster states that industrial hygiene is "a system of principles or rules designed for the promotion of the health of our industrial population." The objectives are the formulation, institution, and promotion of such principles or rules.

Based upon such a concept, the organization and development of a division of industrial hygiene require the close coöperation of many individuals and groups. Bristol¹ has outlined groups concerned as follows:

1. Employee and his dependents
2. Employer
3. Physician and his coworkers, such as dentist, pharmacist, nurse, chemist, engineer, social worker, and public health worker
4. Hospital—public and private—and allied institutions, such as clinics and health centers

To these I should like to add one other, the government—local, state, and federal. No one dares deny that governments have a right to be concerned about the health and well-being of their industrial population. They prosper only in so far as their people prosper financially, physically, and

mentally. A healthy industrial population not only safeguards and improves our national defense, but it also leads to increased production in factories, mines, and on farms, and therefore indirectly to an increased national income.

In order to bring the various groups concerned into a united action, it is necessary that all understand the problem, or as Sayers² has stated, "develop a viewpoint." I believe this viewpoint should be a common one and should involve a consideration of the following:

1. *The worker himself—his physical, mental, and social condition.* This consideration requires the concerted action of the employer, physician, dentist, nurse, pharmacist, and social worker. These people constitute a "team" to take inventory of a working man's health assets.

2. *Environmental conditions.* An understanding of these conditions requires the united action of the employer, the engineer, and the analyst whose findings must never be interpreted without the assistance of the physician and his knowledge of the health inventory of the workers exposed.

3. *Society in general.* This consideration involves "selling" industrial hygiene to all groups possible. It involves carrying the ideas of health

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 25, 1938.

conservation and promotion, sanitation, good housekeeping, and good health habits from the factories and work places into their homes where they may be of value to all dependents of our industrial population. It involves coordinating the activities and interests of employee, employer, hospital, and allied agency, physician and his co-worker, and the government. It involves an interest in, and an understanding of, labor and industrial legislation. And, finally, it requires a keen understanding of the relationship between income, housing, and health as pointed out by Kessler.³

To develop properly any division of industrial hygiene it is essential that an accurate health inventory of our industrial population be made. This requires not only preemployment, but also periodic, medical examinations. These should be thorough and should lead to a complete evaluation of the physical, mental, social, and psychologic condition of the worker. The findings should be used for proper placement; and an effort should be made to determine if there is a relationship between the findings and the worker's occupation, past or present. Neither labor nor industry has accepted fully the value of medical examinations, partly because there have been "chiselers" in both camps and partly because no one has really done a great deal about "selling" the merits of such a procedure. Those industries which have initiated such a policy, employees so affected, and almost all physicians, however, believe medical examinations at regular intervals will help much toward conserving and promoting good health. Page⁴ and others have very effectively emphasized the advantages.

A very forceful illustration of the advantages of preemployment examinations may be gained from figures obtained from one of our large Texas in-

dustries which recently constructed a new plant. When no preemployment examinations were required, their experiences led them to anticipate a cost of \$10,000 for hospitalization, medical care, etc., resulting from injuries and illness arising during the period of construction. They then adopted a policy of preemployment examination, examined 335 applicants, passing 291 as physically and mentally and psychologically qualified for the work. The total cost of medical care, hospitalization resulting from injuries, and illness arising during the period of construction was \$76. Adding to this amount the cost of medical examinations and the salary of a personnel director, there was still a saving of over \$5,000 in this one instance. Although no disagreement exists as to the value of such examinations, there is a definite misunderstanding among physicians and dentists as to who should make them and what should be done about them after they are made.

Physicians, nurses, and dentists can be well divided into three large groups:

1. Public Health
2. Industrial
3. Private or Family

A division of industrial hygiene may well serve as a disease finding agency for such groups as tuberculosis control, venereal disease, malaria, etc., and relay to each group respectively such findings as are of interest to it. Likewise, the local health officer should be advised and be expected to follow up and take care of such public health problems as may exist. This, therefore, would mean a division of industrial hygiene should serve as a clearing house for all other divisions as regards diseases found in industrial employees.

All abnormalities arising out of the nature of the employment should be reported to, and be handled by, industrial physicians and be paid for by the

responsible industry. The average practicing physician does not have adequate time to study the advances made in physical and synthetic chemistry and to keep informed on the possible effects on health of the various materials and chemicals which may be used. This has been convincingly discussed by Legge.⁵

All conditions not directly associated with the nature of the employment should be referred to, and be handled by, the private or family physician and should be paid for by the patient in so far as he is able to pay, but ability to pay must not determine the availability of medical care. No one dares say that only those with contagious and infectious diseases who can pay should receive medical care.

Whether or not a division of industrial hygiene should be responsible for, and make physical examinations is being argued for and against. The merits of such a procedure are well emphasized by the activity in Mississippi under Felix Underwood, M.D., State Health Officer, and J. W. Dugger, M.D., Director, Division of Industrial Hygiene. Physical examinations are made of all factory workers. Such examinations include among the usual routine procedure a tuberculin test, X-ray of the chest of positive reactors, Wassermann, and blood smear for malaria.

An accurate occupational history, as well as a history of disease experience and immunization, is obtained. Those who need immunization receive it. A list of all those who have had typhoid fever is sent to the county health officer, so he may investigate for carriers. Medical findings are made available to the employee, who is advised to see his family physician for an interpretation, to the employer, and to the county health officer. Such a procedure in Mississippi has proved satisfactory. Fisher⁶ and Sappington⁷ have very

forcefully pointed out the benefit of employee health service.

In considering non-occupational diseases and their control, the activity of the E. I. DuPont de Nemours Company and the Caterpillar Tractor Company are of interest. In 1936 the medical department of the former company, under G. H. Gehrman, M.D., Medical Director, made a survey of the employees for syphilis and found 4.2 per cent had positive findings. These results were kept confidential between employee and medical department unless the employee refused treatment. A similar study was made by the latter company under the direction of Vonachen,⁸ and of 10,000 men examined 4 per cent had a positive Kahn test for syphilis. Where industries do not have their own medical department (and this is usually the case because most industries are relatively small), a division of industrial hygiene of the state health department could function. It must be emphasized, however, that under such a plan treatment would have to be provided by the family physician.

Not only should the physician and his coworkers be responsible for good medical examinations—physical, mental, and psychologic—but also they should:

1. *Play a very major part in procuring from industry accurate morbidity, mortality, and accident records.* Without such records there can be no intelligent approach to either the occupational or non-occupational disease problem. Records of absenteeism should be complete with regard to duration, frequency, and cause in each occupation of an industry. In this way only can a definite type of action be indicated. One example of the value of such records was well illustrated by Bloomfield⁹ in his discussion of evaluating the sickness problem needing attention in the iron and steel industry. These records should, of course, be available not only to the medical

department of the particular industry involved but also to public health officials—such as administrators of a division of industrial hygiene—so that the information may be used to conserve and promote health in other industries of a similar nature but without records of absenteeism.

2. *Teach employers and employees proper health habits—mental and personal hygiene.* When we realize that the report on "Medical Service in Industry and Workmen's Compensation Laws"¹⁰ recently published by the American College of Surgeons reveals that for each day lost from work because of occupational disease 60 days are lost because of industrial injury, and 885 days are lost because of non-industrial injury and illness, we can readily understand why a division of industrial hygiene may have difficulty in justifying its existence if it considers its problem to be only that of the study and control of occupational diseases. There can be no doubt that industrial hygiene must broaden its program to be one of industrial health conservation and promotion—a public health program.

3. *Emphasize the value of safe, adequate, and nourishing food and a well balanced diet.* The fads and fantasies of foods and diets affect no group more than the industrial group. The tempo of our age is conducive to "fast living" particularly among our working group. This frequently leads to disturbances of the gastrointestinal tract ultimately ending in fanciful, distorted, and unbalanced diets.

It is also believed by many authorities that the average American breakfast and lunch are entirely inadequate and unbalanced. Such conditions are thought to be conducive to the occurrence of industrial accidents.

4. *Supervise recreation and rest periods—emphasizing the probable relation of fatigue to accidents.* Recre-

ation among industrial groups must not only be encouraged but also be graded and supervised in order to prevent too strenuous exercises or over-indulgence. No one is more qualified to render this service than the medical man.

5. *Insure a safe water and milk supply as well as an approved sewage disposal system—including industrial wastes.*

6. *Supervise a program of accident prevention and first aid instruction.* This activity is usually taken over by other agencies. The "viewpoint" and plans for small industries might well be laid and made by a division of industrial hygiene.

7. *Promote and encourage rehabilitation—the value of which has been pointed out by Kessler.¹¹* This is an activity which has been sadly neglected. As preemployment and periodic medical examinations become more common, a higher percentage of prospective employees are likely to be refused employment. Many of these individuals with minor defects can be rehabilitated, and some agency must assume the responsibility of promoting or sponsoring such activity.

8. *Supervise hospitalization and convalescence.* Many employees, either intentionally or unintentionally, evade hospitalization; and many return to their work from an illness before they are fully restored to health. These individuals may be a hazard not only to themselves, but also to their fellow workers. A thorough medical check-up is very desirable after each illness before regular work is again entered into.

9. *Initiate ideas and institute a program for the reduction in the number of abortions.* The incidence of criminal abortions is unknown. However, all people are agreed that the numbers are enormous. Much of this condition is brought about by a lack of responsible and ethical source of birth control in-

formation. The lack of such information to women in industry who are in no economic position to bear children is deplorable. The solution, however, is still rather remote.

We pass on to the second major consideration—environmental working conditions. The place of the engineer in this field cannot be more effectively discussed than it has been by Bloomfield.¹² I will briefly recall some of the problems. Public health engineers and chemists are concerned not only with determining environmental conditions as they exist, but also with the effect of these conditions upon health. This, therefore, places them in intimate contact with the physician and his group with whom they work hand in hand. Engineers and chemists are also concerned with the effectiveness of control measures.

It has been the procedure in most states to make preliminary surveys of industrial establishments for the location of potential health hazards. This plan has been followed in Texas. The physician, engineer, and chemist can gain more if they make such surveys in company with each other. In these surveys observations are made of the materials used, processes involved, environmental conditions, by-products, finished products, etc. The potential health hazards located are probably identical in most states, and, therefore, Texas might well use the findings of Johnson, *et al.*¹³ in St. Louis. This statement, however, is not intended to detract from their value. We believe the greatest value is derived from the contacts with industry and the knowledge the surveyor gains of industrial processes.

Engineers and chemists of a division of industrial hygiene are really industrial sanitary officers. They concern themselves with problems of:

Lighting—adequacy, intensity, and glare
Ventilation and air space

Dust and fume control
Environmental air sanitation in general
Temperature and humidity
Sanitation—toilets, drinking fountains, wash-rooms, lunchrooms, sewer connections, and plumbing installations
Machine guarding
Protective clothing and devices
Fire prevention and protection
Housekeeping in general

This group of workers holds an enviable position in the general program of industrial hygiene. The tendency has been to emphasize occupational diseases and their control and to pay less attention to those other diseases which perhaps have no direct connection with occupation. The industrial hygiene physician has interested himself more in health engineering than the industrial hygiene engineer has interested himself in the promotion of better health regardless of conditions involved. Industrial hygiene physicians can well afford to absorb from these engineers the enthusiasm and interest which they manifest, and direct the program of industrial hygiene so that it will not only be a public health engineering program, but a public health program in the broad sense.

It is obvious that not only industrial hygiene physicians, but engineers too, must acquaint themselves with the economics of labor and industry as well as with legislation affecting these same groups. This problem requires a thorough understanding not only of environmental working conditions and the probable effect upon health, but also of human psychology. Sappington¹⁴ states that in 1935 legislation relative to compensation was introduced in over 40 states. Undoubtedly much of this was ill advised. Eleven states now have a general coverage act, 10 a schedule, and 2 a special coverage, 31 have a general designation for employments covered; 9 enumerate hazardous employments covered; 2 designate employments for gain; 4

enumerate extra hazardous employments; and 1 has a very limited classification covered. Thus we have a rather confusing system of coverage. It appears that no one would be in better position to pass on the merits of proposed or existing legislation than a division of industrial hygiene, and any legislative body certainly should avail itself of such guidance.

The third major factor to consider in formulating a program of industrial hygiene is the reaction of society in general. Because of the large number of groups and people involved, the task of developing a common viewpoint, of selling a program, and of making it acceptable to all groups is very difficult. What industry approves, certain groups of labor will automatically disapprove without just cause. What insurance companies recommend is often not satisfactory to industry. What is agreeable to all other groups may not be agreeable to "organized medicine." The task of bringing all groups together requires tact, diplomacy, firmness, sympathy, knowledge, understanding, and a fair sense of judgment. It requires the services of individuals who might be classed as "charming borrowers."

There are now 21 states and the District of Columbia which have compensation for occupational diseases in some form. Other states are certain to follow. Whether these states should be guided by their respective divisions of industrial hygiene in electing specific or general coverage may be disputed, but everyone must realize that a division of industrial hygiene will play a very important part in whatever program is adopted.

Finally, we come to the question of income and housing and the effects each may have upon health. Is it possible that we are approaching the entire health program from the wrong end? Can any permanent good arise

from any program we are now promoting in industrial hygiene unless, first of all, the economic status of the worker is improved? If workers were financially able to provide themselves and dependents with proper and adequate food, clothing, shelter, sanitary facilities, medicine, and medical care, would our task not be much simpler? I shall leave this for you to answer.

It is not to be implied, however, that any division of industrial hygiene should promote, sponsor, supervise, or carry out such a program as we have outlined. The program given represents our view of the problems existing in industrial hygiene. Those industries having their own medical services really have, or at least should have, units of industrial hygiene functioning according to the broad interpretation. Their experiences, however, should be made available to other groups. Those industries having no medical services (and this includes a greater number of them) must be provided for either through their own efforts individually or collectively or through those of a government. At any rate, some central agency must assume the initiative. Such a plan will lead to uniformity in form of reporting sickness, be it occupational or otherwise; in control measures; in medical examinations with subsequent placement of men in jobs for which they are fitted; in compensation and rehabilitation; and finally in disseminating knowledge for health promotion.

These are the objectives toward which George W. Cox, M.D., State Health Officer of Texas, is striving to direct his Division of Industrial Hygiene.

In summary, it appears that a well balanced and properly functioning division of industrial hygiene should:

1. Be a part of a health department.
2. Consist of personnel trained to think of industrial hygiene as a public health problem

involving not only health conservation in its broad sense, but also health promotion and rehabilitation, be it physical or mental.

3. Consist of, or have available for consultation and assistance, physicians, dentists, engineers, chemists, nurses, social workers, educators, and, last but not least, competent administrators.

4. Have a part in the promotion and guidance of the various activities discussed even though it may not carry out the actual work through its own personnel.

5. Act as a clearing house for all agencies as regards finding of diseases in our industrial population.

6. Promote a health program for the 49 million wage earners of our country, a group entitled to a better health service than they now receive.

Is the Lowering of the Death Rate Due Principally to Curative Medicine or to Preventive Medicine?

"Preventive medicine . . . with hygiene and social progress, is playing a more important rôle than curative medicine in the preservation of human life." This is the conclusion which Dr. René Sand draws from a study of the causes of the 28 per cent decrease in the general death rate in Belgium from 1910 to 1935. The importance of preventive medicine is generally recognized in certain diseases, such as smallpox, but the part of preventive medicine is less commonly realized in such conditions as respiratory infections, tuberculosis, and puerperal infections. Social legislation, improvement in conditions of housing and industry, increase in salaries, education, improvement of hospitals, increase in the number of clinics and sanatoria, and the preventive work of the doctor and

the visiting nurse have all helped more to decrease the death rate than have progress in therapeutics and diagnosis. However, Dr. Sand points out, it is becoming increasingly difficult to separate preventive and curative medicine because much of modern treatment has a preventive effect. Dental care prevents dental abscesses and pyorrhea; syphilitic treatment prevents the complications of the later stages and also the communication of the disease to others; when the doctor prescribes a diet, he thinks not only of curing the disease, but of the nutrition of the individual afterward. For such reasons as these, preventive and curative medicine are separable only in theory, and the importance of curative medicine cannot be minimized.—*Imprim. Med. Scient.*, Sept. 18, 1938. Bruxelles.

Value of Phosphatase as an Indicator of Pasteurization*

F. W. GILCREAS

*Division of Laboratories and Research, New York State
Department of Health, Albany, N. Y.*

THE phosphatase test has found a wide application in the control of pasteurization of milk. In New York State it is being used as a routine laboratory procedure in the supervision of pasteurizing plants as well as in the sanitary control of milk supplies. Continued experience indicates that the inactivation of this enzyme can be used to detect improper treatment of milk almost without failure.

Our early studies of the modified Kay and Graham test¹ indicated that a value of 0.04 mg. of phenol per 0.5 ml. of milk was the average maximum limit for milk completely pasteurized at 143°F. However, variations in the operation of pasteurizing equipment, particularly in the time and temperature of preheating and in the methods of cooling, affect the degree of inactivation of phosphatase. We now regard as properly pasteurized a milk which has a phenol value of less than 0.05 mg. per 0.5 ml. The plan of interpretation adopted considers as slightly underpasteurized milk with a phenol value of 0.05–0.08 mg. per 0.5 ml.; as underpasteurized, that with a value between 0.09 and 0.15 mg. per 0.5 ml.; and as an indication of gross under-

pasteurization, a value of 0.15 mg. per 0.5 ml., or greater.

It was also thought that the inactivation of phosphatase could be measured with sufficient sensitivity to detect accurately a reduction of 5 minutes in the holding time at 143°F., a lowering of the temperature of heating by 1°, or the addition of 0.1 per cent of raw milk. In the comparative study conducted for the Association of Official Agricultural Chemists² it was found that this precision was not attained consistently in the examination of samples representing such treatments. During a prolonged period of preheating such as is practised in many pasteurizing plants, the enzyme is progressively inactivated to such a degree that the phenol value after a technical 25 minute holding period is indicative of complete pasteurization, although the legal requirements for pasteurization at 143°F. have not been met. A drop of 1° or more in temperature of heating was detected in this comparative study in 92 per cent of the samples so treated. Pasteurization at 142°F., therefore, necessitates the establishment of a code of phenol values which differs from that used for pasteurization at 143°F.

Neither of these variations in treatment is of practical importance. The addition of 0.1 per cent of raw milk,

* Read before the Laboratory Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 28, 1938.

TABLE I

Phosphatase Values of Known Samples of Pasteurized Milk (143° F.), of the Cream Separated by Gravity at 40°± F., and of the Skim Milk

however, may be of great significance since even such an amount of contaminated raw milk would readily contaminate the pasteurized product. In the comparative study² the various laboratories detected 0.1 per cent of added raw milk in only about one-third of the samples so treated. A tendency in many pasteurizing plants to overheat the milk slightly, reduces the phosphatase content sufficiently so that the addition of this amount of raw milk gives a phosphatase value which falls within the limits established for complete pasteurization. Quantities of added raw milk greater than 0.1 per cent apparently, however, can always be detected by the laboratory test.

Whereas the inactivation of phosphatase has proved a useful indicator of pasteurization of milk, persistent reports have been received that samples of cream separated after pasteurization frequently give a reaction of underpasteurization, even when plant inspection indicates that the treatment was adequate. No instances have been reported in which cream, separated from raw milk and then properly pasteurized according to standard procedures, failed to give a definite reaction of pasteurization with phenol values definitely below 0.05 mg. per 0.5 ml. Since the earliest evidence of failure of the test in the examination of cream was concerned with samples which had been separated from pasteurized milk by gravity, we attempted some analysis of the problem by examining 139 samples of known pasteurized milk collected by

the staff of the Bureau of Milk Sanitation. The whole sample was first thoroughly mixed and a 10 ml. portion removed for subsequent examination. The remaining volumes were allowed to stand for 48 hours at 40°F., when portions of cream and skim milk were removed. The residues were again thoroughly mixed and additional portions taken for examination. As shown in Table I, only 75.5 per cent of the samples of cream had a phosphatase value indicative of pasteurization. In all cases the phenol values of the whole milk and the skim milk indicated adequate pasteurization. The phenol value of the milk remixed after separation were always found to be the same as that originally obtained.

A similar study has been made of cream separated mechanically from known commercially pasteurized milk, also collected by the Bureau of Milk Sanitation. Temperatures of pasteurization were 142°-143°F. for 30 minutes, 160°-169°F. for 15 seconds, and 180°-189°F. for 15 seconds. The usual temperature at which this cream was separated was between 90° and 110°F., but samples were also collected representing temperatures of separation between 90° and 60°F., and less than 60°F. Irrespective of the temperature of pasteurization or of separation, the phosphatase value of the mechanically separated cream increased with alarming frequency to a value indicative of underpasteurization and, in a few instances, even of gross undertreatment. The phosphatase

values of the corresponding whole and skim milk indicated proper pasteurization. In order to eliminate the possibility that the cream had become contaminated during the process of separation with some substance other than phosphatase which would react with Folin's reagent, a control test was made on all samples examined. These were without exception low and did not differ from the control values found on examination of the whole milk. The results are given in Table II.

Representative samples of the cream which had a high phosphatase value after separation were then repasteurized in the laboratory and again tested. In all cases a low value indicative of complete treatment was found, showing that the substance causing the high reading in separated cream is heat labile.

In order to obtain further information concerning the effect of temperature of separation, we examined a few samples of cream separated by gravity from pasteurized milk stored at temperatures of 98°F., 68°F., and 40°F. To avoid interference by bacterial growth at the higher temperatures, the samples of milk were each allowed to stand for 2 hours to permit sufficient cream for the test to rise. The results, given in Table III, again show a tendency for the phosphatase value of cream to increase beyond that of the original milk. As indicated, the whole and skim milk were found properly pasteurized in all cases.

A sufficient number of samples has

not yet been examined to indicate the frequency of this discrepancy between milk and cream. However, the data suggest that caution must be exercised in the interpretation of the results with cream, particularly since much of that from small pasteurizing plants is separated from excess pasteurized milk. When the laboratory reports indicate inadequate heat treatment of cream samples, thorough inspection of the pasteurizing process should be made before the product is considered actually underpasteurized. It is difficult to explain the cause of this increase in phosphatase content. It is possible, however, that since the enzyme is not completely inactivated at 143°F. for 30 minutes, or 160° or 180°F. for 15 seconds, the fat particles in rising from the milk, either under action of gravity or during mechanical separation, absorb and concentrate in the cream layer sufficient phosphatase to give a reaction of underpasteurization.

In examination of this point, samples of raw whole milk, cream, and skim milk were collected at the separator of a commercial dairy. In order to permit accurate measurement of the phosphatase content of these samples, 0.3 per cent and 0.5 per cent dilutions of each in pasteurized milk were prepared. The results of this experiment, given in Table IV, indicate clearly that in the presence of active enzyme in the whole milk there was a marked concentration of phosphatase in the cream fraction after separation.

It is essential that further study be

TABLE IV

pointed out, for all practical purposes of quarantine and control, measures against the *Aedes aegypti* have proved sufficient and probably will suffice in the future. The discovery, however, furnishes much food for thought and makes us realize more than ever the rôle which insects have played in the past and now play in the transmission of diseases.

We have several times pointed out the apprehension which exists over the possible spread of yellow fever to countries like Egypt and Asia, the new factor in this case being the tremendous increase in travel by airplanes. It is evident that once again must we revise not only our ideas but to a certain extent our methods in the control of certain diseases. We have felt sure that yellow fever would never again gain a foothold on the North American continent. We can still hold to this belief with a large degree of confidence, the more so since heretofore possible and unsuspected dangers have been detected and can be guarded against.

APPRAISING LOCAL HEALTH WORK

THE publication of the *Appraisal Form for Local Health Work* by the American Public Health Association¹ adds another contribution to the impressive list made by the Committee on Administrative Practice and indicates further advance in the development of appraisal methods. It is noteworthy that public health programs of rural counties have progressed sufficiently to cause the committee to prepare a single Appraisal Form to be applied, with some adaptation, in both rural and urban areas. This Form combines selected features of the *Appraisal Form for City Health Work*, first printed in 1925, and the *Appraisal Form for Rural Health Work* later issued in 1927, and includes revisions and additions of new indices in line with tested experiences.

Surveys of health conditions were undertaken in England nearly a hundred years ago, Chadwick's report in 1842 on "Sanitary Conditions of the Labouring Population of Great Britain" being well known. The first sanitary survey in the United States was made by the Massachusetts Sanitary Commission, headed by Lemuel Shattuck, in 1849.² Probably the first step toward the development of local health appraisal methods was the preparation in 1875 of a List of Questions relating to the sanitary condition of a city or town, by a committee of the American Public Health Association. The Chairman, John S. Billings, M.D., explained the purpose as follows: "These questions are intended to obtain, as far as possible, the information which would be desired in estimating the healthfulness of a given place, and to ascertain the local and especially the preventable cause of disease at that point. Facts and not opinions are desired, and the questions are drawn up in that point of view."³ While quite complete for stock taking of sanitation facilities and procedures, these questions naturally omitted many of the features now recognized as of primary importance in a modern public health program.

A new era in community studies began in the early years of the present century. The Pittsburgh survey⁴ initiated in 1907, primarily as a social and educational

undertaking, was followed by the taking of community case histories throughout the United States. Furthermore, in response to the official requests of governors and mayors for an appraisal of the health machinery which was so important a part of their respective governments, the Surgeon General of the Public Health Service assigned physicians of his staff for this purpose, with valuable results in the broadening of legal authority and the enlargement of functions of state and local boards of health.

Based on the results of extensive surveys and on group judgment of health officers and other public health workers, the Committee on Administrative Practice developed the Appraisal Form to facilitate the analysis of community health service against a background of social and health conditions. This measuring rod aims to help in determining the adequacy of public health work in relation to the magnitude and type of local problem. The Appraisal Form does not attempt to determine with finality the relative importance and proper place of all local problems. It selects certain problems which experience has shown are common in varying degree to most communities and uses the services rendered in these fields as a gauge of the health efforts of the community in a particular field. The new edition consists broadly of three parts: descriptive survey of facilities, appraisal of health activities, and selected indices of community characteristics related to health. This instrument enables a health officer or a surveyor to take account of stock periodically, and is a valuable adjunct to personal field observations.

An important contribution was also made to the survey method in 1936 through the development of objective indices of health in relation to environment and sanitation by a member of the staff of the Health Organization of the League of Nations.⁵ The plan involved an attempt to formulate a series of objective data which are deemed desirable in order to arrive at a more complete and a more precise appreciation of health conditions than is ordinarily obtained. This system does not establish a unit rating, but is rather meant to indicate, describe and measure local problems. In October, 1938, the Committee on Health Indices of the League met in Geneva and revised the schedule which had been utilized for two years. The anticipated next step will be the application of the new schedule to a number of health jurisdictions in various parts of the world.

With the advancement of public health and the changing problems of society to be considered, the administrator is faced with the responsibility of analyzing community programs and of determining relative values so far as practical. Application of appraisal methods and scrutiny of health indices may assist materially in the evaluation process.

SANITARY DISPENSING OF BEVERAGES

TWENTY years ago an article in this *Journal*¹ called attention to the dangers of contaminated glasses and dishes in the spread of respiratory diseases. Since that time, much progress has been made in the control of this hazard by appropriate legislation, by the development of chemical and physical methods of sterilization, and, more recently, by the use of ultra-violet rays having bactericidal powers.²

The magnitude of this problem is indicated by the continued widespread use of glasses and other eating utensils in public restaurants, soda fountains, taverns, and roadside stands. It is estimated, for example, that some four and a half billion bottles of carbonated beverages are sold annually in this country, while more than ten billion glasses of draught beer are consumed in the United States every year. Add to these figures the glasses and cups used in public places for milk, coffee, tea, fruit juices, and other beverages, including water, which is still favored by some consumers, and the total obviously reaches a staggering figure.

In addition to the problem of adequate cleansing and sterilization of the utensils that come in intimate contact with many individuals, there is also the sanitary problem of proper dispensing of various beverages from bulk containers. Despite the growth in popular favor of bottled and canned beer, for instance, draught beer over the counter still accounts for considerably more than half of the sales of this farinaceous product, and newly developed methods for cooling its containers and retaining its pleasing flavor may make this beverage even more popular.

While the old-fashioned type of loose milk has been prohibited by law in most communities, devices have been perfected for the hygienic dispensing of pasteurized milk from bulk containers in restaurants. After more than three years' study, seven such devices have been approved by the Health Department of New York City, and are being installed in public eating places at a fairly rapid rate. There is no reason why such devices should not be permitted and employed if it can be demonstrated to the satisfaction of discerning health officials that in construction and operation such devices will consistently safeguard the public health.

The essential features of such sanitary dispensing gadgets are simplicity and ease of operation. They should be made of materials that not only resist contamination and are non-toxic, but are so constructed that they may be frequently and easily disassembled and quickly and effectively cleansed or sterilized in boiling water or appropriate chemical solutions.

The formulation of standards for such devices is, of course, only a part of public health control. Adequate and reasonable enforcement by health authorities of hygienic practices in the dispensing of these billions of beverages is equally significant.³

PUBLIC HEALTH EDUCATION*

"Short Words Pack a Punch"—

A master writer, Gelett Burgess, under the above title, makes a plea and points the way. The writer and speaker on health should read the whole of the short article. Here are two selections:

This is a plea for the use of more short words. For through the lack of them our speech grows weak and may hold more sham than true thought. Long words are apt at times to hide or blur what one thinks; but short words say just what they mean, and do not leave you in doubt. They are clear and sharp, like signs cut on a rock.

Of course, if one has deep or strange or high, shrewd thoughts to tell, one must use long words more or less; but if you would like to say things with force, it is well to learn first to use short words as much as you can. It will make your style crisp and give it zest when you talk or write.

Friend, read the Good Book. Read the tale of Ruth, read of Saul and Lot, and all the rest, and see how wise and deep are the short crisp words of our great tongue. To be sure, the tales are not told all in words as short as those I use here, but they are all good old words that are couth and yare and there are few long ones. When they tell a tale you can see what goes on as if in a play, by the sheer spell of plain, free speech that can say what it means to a mere child and not be lost.

Short words are words of might.

In *Your Life*, 354 4th Ave., New York, N. Y. Nov., 1938. 25 cents.

Pictures in Continuity—Not a picture to tell this, and another to tell that. But a group of pictures to tell this and this about that. Such is the practice of more and more newspaper rotogravure editors, as brought out in

an article in *Editor and Publisher* (Times Bldg., New York, N. Y., Dec. 17, 1938).

One editor says:

"I don't mean . . . that every picture in our section has to be part of a continuity series. We use a good many single shots when we think we have shots that are interesting. But we are aiming at one goal, to make every picture tell a story, just as we attempt to make every block of type tell a story."

A few hospital and other annual reports have adopted this technic, but doubtless more health agencies could do the same.

Another editor emphasizes a point in handling pictures:

"In my format I have eliminated all ginger-bread cut-outs and designs around pictures, all ovals and trick make-up. I make each spread of pictures tell a story, and the photographs are laid out in simple form so that the eye will not be attracted from the picture itself."

Frequent examples of picture continuity idea will be found in *Life*, *Look*, and other picture magazines.

Continuity would do a lot for pictures in exhibits, but there pictures must have size as well as story. At Kansas City, we had pictures too small to tempt anyone even to look for a story.

Man in the Museum—Under this title, Dr. Bruno Gebhard, of the American Museum of Health, presented a paper before the American Museum Association.

A few selected paragraphs:

My personal feeling is, and it is based on more than ten years of very detailed experience, that a Museum on Man which is only of an explanatory type similar to most of our biological or anthropological divisions has

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22nd St., New York, N. Y.

only a very small appeal to the masses of the people. What people really want to know is "How shall we live?" . . .

Man as a living organism makes it necessary to look for special methods of presentation. Whenever it is possible, three dimensional models, animated diagrams and personal participation should be included. The personal participation may start with the invitation "please push button," instead of the old "Don't touch!" The visitor may test his own strength of the muscles, the capacity of his lungs, the absence or presence of color blindness, or the power of vision. There may be a demonstration of the beating of the visitor's own heart, its frequency and its very dramatic sound, as it has been done in the last Paris Fair. The personal participation may be very simple, but it always teaches a real lesson. It aids in fixing the message of the special item in the mind of the visitor. Personal participation is also a good remedy against museum fatigue.

We all realize how important it is to have motion in our exhibits, sometimes in combination with light such as a model of the Circulation of Blood. Animated diagrams have proved their educational value if logically related to the subject matter. Wherever we can we should visualize biological figures which we tell the public. The amount of air a person breathes through his lungs in one day can be shown by a cage made from wire hanging from the ceiling.

The Transparent Man—a life-size figure which shows by lights the location and relation of the different organs—is at present unsurpassed as a feature of the three dimensional model. . . .

More or less, we are not allowed to show Man in his body structure only. We have to demonstrate at least the function of the body. In other words, we should not have a section on "Skeleton and Muscles," but on "Walking and Working." We have to make a stronger attempt to show Man in his mental construction and in his emotional make-up. If we show the fundamentals of personal biology we should then show that nobody is in this mold by himself—that we all are only a link in a chain, that we all are born and live in families, that we have ancestors and heirs. . . .

Right or Wrong, or Which Is Which?—With all the varied forms of question and answer broadcasts, it seems a pity that health is not given its opportunity in perplexing radio

audiences. Anatomy, physiology, sanitation and hygiene, and related special sciences should furnish a wealth of good material.

A file of *Hygeia* alone should provide material for several different broadcasts for several years.

To Be a Puppet Showman—There are many books on puppetry. One of the best for amateurs is "Be a Puppet Showman," by Remo Bufano. Century Co., New York, N. Y., 1933. \$2.50. The author is a master puppeteer, and he is a sympathetic guide to the beginner. His book is easy to read, and his information is easy to use.

It is hoped that the combination of craftsmanship and showmanship offered in puppetry will lure some health workers. It is a hobby with health education possibilities.

Also we hope that several health agencies will test collaboration with school and crafts groups to enlist children and young people in puppet making with health education as a by-product.

Bufano emphasizes the long history of puppets in presenting "serious" plays. Puppet plays need not be slapstick, and they can be given with a surprising appeal to adult audiences.

Health Education in Y.W.C.A.—Major emphases for 1938-1940 are announced by National Board, Y.W.C.A., 600 Lexington Ave., New York, N. Y.

The health education program in the Association should include individual service on personal health problems; educational programs relating to health and recreation; activities that build health and develop skills in recreation and the provision of opportunities for continuing participation in these recreational activities. Responsibility for this program is shared by all groups in

the association. Such a program constitutes a legitimate cost to the association and should be so budgeted.

The emphases for the biennium will be:

- a. Nutrition, relaxation and sex education.
- b. Work on community health problems and coöperation with public and private health agencies.
- c. The study of administrative practices in relation to program trends.

Coöperative Publication in New Jersey—Some 19 local health departments in New Jersey participate in a joint publication plan directed by John Hall, of Freehold, N. J., Executive Secretary of the New Jersey Health and Sanitary Association.

By this plan each department issues, in its own name, a 4 page illustrated bulletin five times a year. The cost is \$12.50 per issue, for 500 copies; \$20.00 for 1,000; \$1.00 for each added 100; specially prepared pages, each \$4.00 in addition.

For two years the State Department of Health has paid for three-fifths of the cost.

Doubtless, for many readers the limited size is an advantage.

"When Everyone Knows"—This is the title of the annual report of Canadian Dental Hygiene Council, 170 St. George St., Toronto, Ontario.

An organization diagram shows a wide range of coöperative effort. A variety of oral hygiene material is listed. An Ontario mouth hygiene campaign is described.

The objectives of the Council:

When every person in Canada knows what every physician, dentist, and health worker knows—that diseased teeth are one of the most common causes of ill health, and further, when everyone knows what scientific findings declare—that diseased teeth may be prevented through proper diet, careful attention to mouth hygiene, and early operative treatment, all of which involves very little financial expenditure—then the Canadian Dental

Hygiene Council will feel that it has fully performed its task, for this is what the council is striving to teach.

Who Wants To See Pictures?—Or, examples of charts, or interesting cover pages, etc.? We could use more of such material if our readers will send it in? See address at foot of this page in every issue of the *Journal*.

"If Any Money Is Left Over"—In "Four Years of District Health Administration in New York City," by Dr. J. L. Rice and Dr. M. W. Barnard, in *Milbank Memorial Fund Quarterly*, 40 Wall St., New York, N. Y. (July, 1938), under "Health Education":

Of all the district services the one which is probably best suited to localization is health education. Effective teaching of health work must be based on an intimate understanding of the people to be taught. Subject matter must be adapted to many interests, traditional thought patterns and levels of intelligence. Health education seems also to be the field of public health which is least thoroughly geared into public health programs throughout the country. Too often it is the thing to be done if any money is left over. Trained personnel, tested procedures, and funds are inadequate. Four years of district experience have shown both the urgent necessity for organized health education among the people and some of the effective ways in which this can be done on a localized basis. Development of this work is one of the outstanding plans in the district program.

Check Your Shipping Department—Especially in quite large organizations the shipping of health education material by mail or otherwise is far removed from the office which lovingly, and with meticulous care, plans and prepares the posters and other publications.

Some such material received by the writer has arrived in bad shape because of careless handling in the shipping department, or through efforts to save a small fraction on the cost of the printed matter.

One practice is to mail a single poster, or a small lot of posters, rolled in a

flimsy cardboard cover which is most likely to be crushed in the mail.

Another disconcerting practice is to use a too small mailing tube into which the poster or large printed piece must be crowded by the shipping clerk, so that in some cases the tube must literally be removed in pieces if the enclosure is to be taken out whole.

Anyway, the rolling of a bundle of assorted pamphlets, broadsides, and posters gives the recipient an annoying job of getting each separate item rolled flat before it can be examined.

Again, those whose monthly bulletin or health journal is rolled for mailing might well consider if the loss of good will is a fair equivalent for the slight saving in cost.

To help make sure as to how matters go in the shipping or mailing rooms, one might order sample shipments to one's home address, as well as to the addresses of several friends.

And it may be well to bear in mind that in the course of time, with changes in personnel, shipping practices may be changed radically without official intent.

It Can Be Done — Government health education printed matter can be made to look interesting. For proof see a new folder so readable in appearance that you won't believe it came from the U.S.P.H.S. until you see the modest credit line at the foot of the last page.

"Syphilis: It's Cause—It's Spread—Its Cure," is an 8 page folder prepared to supplement efforts of physicians and clinics.

"It is clear. We tried it on patients at a city clinic, on a workers education group, on a grade school age group, on college students. We revised it until it answered their questions in a way they would understand. Then we added the pictures to help drive home the story."

"It is inexpensive. It may be secured from the Superintendent of Documents in Washing-

ton, D. C., for \$1.00 per 100 copies. In smaller quantities five cents each. But give one to each patient on the occasion of his first visit and it should save many cases for many treatments."

Making a Bibliography More Useful—What is a bibliography for? How can it be made to serve the desired purpose?

These questions arise more and more frequently as we examine the reading lists included with reports and other publications.

The latest is a bibliography accompanying "Tuberculosis in Philadelphia," by A. M. Lowell, Research Secretary, Philadelphia Health Council and Tuberculosis Commission, 311 S. Juniper St.

The last 2 of 54 mimeographed pages lists articles, pamphlets, and reports:

... sources which will permit a more intensive study of the tuberculosis problem in Philadelphia.

Of the 24 references 11 or 12 contain Philadelphia data. The other references would help in the "intensive study" of any other city as much as in further Philadelphia studies. *Would it not have been worth while to have indicated the sources of local data?*

Without guessing who might make a further "intensive study" in Philadelphia, *would it not be helpful to have added concise annotations to point out the significance of at least some of the general references?*

DATES AHEAD

Are you preparing for a future commemoration of your department, your agency, or of some special aspect of your activities? An editorial, "Historical Data and Anniversaries," in *Hospitals* (Am. Hos. Assn., 18 E. Division St., Chicago, Ill., Jan., 1939) should interest more than hospitals. Two paragraphs say:

Few hospitals preserve the data that make for historical record. A metal fire-proof

cabinet should be provided for minute books, photographs, portraits, newspaper clippings, and data referring to the contemporary activities of the hospital.

The hospital management preparing for the celebration of one of these periods should be extremely grateful to predecessors who have preserved the record of progress.

Anniversaries may be commemorated in many ways. Ample historical data; moving pictures; exhibits of hospital scenes at the time of opening; portraits of founders; set-ups of interesting exhibits, such as an operating room of the eighties alongside of an operating room of the present day; pathological laboratories contrasting the two periods; comparative exhibits of old and new equipment; a period exhibit of nurses' uniforms on manikins or dolls, all serve to show the advance in hospital standards.

"Social Hygiene Day" activities will be continued through February in many communities.

In March, 1877, the first visiting nurse started on her rounds.

St. Patrick's Day, March 17, need not be overlooked in writing timely health material.

And then comes Early Diagnosis Campaign, with possibilities in co-operation from most health agencies.

April 1 may prompt reminders of how easy it is to fool oneself in health matters.

FOR REFERENCE AND EDUCATION

"Dry Skim Milk," by Bureau of Home Economics, Dept. of Agriculture, Washington, D. C. *Free*.

Nursing Information Bureau, 50 W. 50 St., New York, N. Y., will send free samples of the following folders:

"Safe Nursing Care" . . . "8-Hour Day" . . . "Wanted: A Real Nurse, an R.N."

"Safety and Sanitation in Institutions of Higher Education," by Dr. James Frederick Rogers, Office of Education. Supt. of Documents, Washington, D. C. *10 cents*.

"The Truth about Cancer." A chapter to a page. Simple, clear. New York State Dept. of Health, Albany, N. Y.

WANTED

A group of graduate students listing health motion pictures and film strips. Send information to Frank J. Mayer, 140 W. Medical Bldg., Ann Arbor, Mich.

A "Guide to Information about Dental Health" is a tentative printed edition, submitted for examination and use test. Intended to carry "in condensed form information of primary importance," the 8 page folder is designed "as an aid to social workers, dental hygienists, school teachers, nurses, and community health workers." If you will join the corps of critics, ask New York Tuberculosis and Health Assn., 386 4th Ave., New York, N. Y., to send you a copy.

BOOKS AND REPORTS

Military Preventive Medicine—
By George C. Dunham, M.D. Carlisle Barracks, Pa.: *Army Medical Bulletin* No. 23, *Medical Field Service School*, 1938. 1198 pp. Price, \$2.50.

The first edition of this book appeared in 1930. The demand for a third edition is a proof of its practical success. It has also met with general favor at the hands of reviewers so that we welcome this new edition which has been revised and brought up to date, and is in every way an admirable book.

The Foreword by the Surgeon General of the Army points out that the military environment shapes the policies of practical sanitation. Measures applicable in the home or in civil communities are often found impracticable in the military service. The difficulties encountered, however, are overbalanced by the opportunity which one has in the military service for the practice of preventive medicine and sanitation and the fact that measures are generally under the control of the officer in charge and can be enforced.

Obsolete material has been deleted. Though it is written from the military standpoint, the underlying principles are the same as in civil practice, and both military and civil officers will find this volume very useful.

The arrangement of the book is excellent and each section is treated adequately. Special attention is given to nutrition. There are good sections on water purification, food control, meat inspection, inspection of poultry, eggs, and fish, dairy and milk plant sanitation, mess sanitation, waste disposal, sewage treatment, etc. It goes without saying that the control of insect-borne diseases is prominent. We owe much

to the officers of the Army for what they have taught us concerning insect-borne diseases. There is also a chapter on Vital Statistics which seems adequate for the purpose. There are six appendices which give the caloric value of human foods, foods which are sources of protein and mineral elements and vitamins, and score cards for dairy farms, pasteurization and milk plants.

The author holds that yaws is quite similar to syphilis, responding positively to the Wassermann and Kahn reactions. He regards alastrim as probably an aberrant form of smallpox.

The book is excellently gotten up and well printed. It is abundantly illustrated with some colored charts, notable among which is one of the reactions of smallpox vaccination which was obtained from the Commissioner of Health of Baltimore, Md. Altogether the book can be recommended unreservedly. The remarkably low price at which it is sold is due to its being an *Army Medical Bulletin* published under the authority of the Secretary of War.

MAZÏCK P. RAVENEL

Introduction To Motherhood—
By Edwin F. Patton, A.B., M.D. South Pasadena, Calif.: *Commercial Textbook Co., Ltd.*, 1938. 137 pp. Price, \$1.50.

It is recognized generally that maternal and infant hygiene depend to a considerable extent upon prenatal care and instruction. Dr. Patton in this little textbook carries the educational process a step or two backward to the adolescent and preadolescent periods where first serious questions are being raised about sex and its relation to motherhood and fatherhood. While this

book is designed to fill a need for suitable instruction in junior and senior high schools, it might well be used, as Dr. Patton suggests, by progressive mothers in introducing their preadolescent daughters to sound ideas of motherhood.

The book is written in an easy colloquial style using words that have an exact meaning. No attempt is made to camouflage the meaning with artistic, dramatic, or puerile phrases. The chapter on "The Child" contains helpful suggestions on child hygiene. Each chapter is followed by a review questionnaire which will assist in fixing the most important points in mind. A glossary of terms completes the text.

RICHARD A. BOLT

Estuary of the River Mersey. *The Effect of the Discharge of Crude Sewage into the Estuary of the River Mersey on the Amount and Hardness of the Deposit in the Estuary. Water Pollution Research Technical Paper No. 7. Department of Scientific and Industrial Research. London, England: His Majesty's Stationery Office, 1938. 337 pp. Price, \$8.00.*

The effect of the discharge of large volumes of untreated sewage on the deposition of solid matter in the Estuary of the River Mersey (England) has been a matter of controversy among the local interests for many years. In 1932, the interested authorities invited the Department of Scientific and Industrial Research to undertake an investigation to determine the effect of such discharges "on the amount and hardness of the deposit in the Estuary." Among other things to which the referring authorities agreed was that "on the issues of scientific facts the results of the investigation should be accepted as conclusive."

The investigation took about 4 years and was necessarily concerned with careful studies of the discharges into

and their distribution within the Estuary; mud sources, composition and deposits; sedimentation rates of mud and mixtures of mud and sewage; the effect of stirring on aggregation and sedimentation; erosion and dredging; and physical changes in estuary channels and banks.

The conclusion of the work and study was that crude sewage discharges had no appreciable effect on the amount and hardness of the deposits in the Estuary.

ARTHUR P. MILLER

A Textbook of Bacteriology—
By Thurman B. Rice, A.M., M.D. (2nd ed.) Philadelphia and London: Saunders, 1938. 563 pp. Price, \$5.00.

This book contains 58 chapters, 5 appendices, an index, but no bibliography. In the preface the author states his feeling that the success of the first edition in two years has demonstrated that the medical student needs a relatively simple text that he may be expected to master in one semester, and revision has aimed merely to bring up to date, clarify, and correct certain passages. A bibliography has been rejected on the premise that students do not read references unless specially assigned by an instructor.

The author has largely omitted theoretical discussions of controversial subjects. The technical processes described in detail are only those which may be carried on by the practising physician, and more complete instructions than is usual in such textbooks are given for taking specimens, sending them to a laboratory, and interpreting the results obtained. The point of view of the author is better understood when it is known that he has been the director of a central state health department laboratory.

It is apparent that the author throughout is writing a reference book for the physician who wishes a short and non-technical review of bacteri-

ology; consequently the book differs greatly from most of the well known textbooks of bacteriology. It is written in a style that might be expected from a physician, author, and teacher who has a penchant for putting scientific facts into popular language. Certainly the presentation is original. While the book seems excellently suited for use by the medical student and the practising physician in the manner that "pleasure reading" is now assigned to pupils in our high schools, its use as a textbook would need to be supplemented by a very complete lecture course.

Morphological descriptions are brief. Bergey's classification is used rather consistently. Technical terms are concisely but, on the whole, rather well defined. There are some inaccuracies in the book. Perhaps too much emphasis is given to disinfection and there is altogether too much use of trade names. The many simple yet illustrative drawings and the somewhat unusual photographs add to the value of the book and differ from those so frequently seen in other textbooks. Many practising physicians would find this book useful for frequent reference.

FRIEND LEE MICKLE

The Bacteriological Examination of Water Supplies. *Report on Public Health and Medical Subjects No. 71. Ministry of Health. London, England: His Majesty's Stationery Office, 1937. 38 pp.*

This monograph was prepared by a committee of eight whose names separately and collectively command the respect of American workers in the field of water bacteriology. The object is to prescribe a standard procedure. The recommended examinations include plate counts at 20°C. and 37°C. and a coli-aerogenes count. Directions are also included for detection of fecal streptococci, *Cl. welchii* and bacteria of

the typhoid-paratyphoid group. While much of the technic differs little from that in use in the United States, the recommended media for the 37°C. plate count and for the coliform group are those of MacConkey. The essential difference is in the use of commercial sodium taurocholate in place of meat extract.

Appendices contain details in regard to sampling, apparatus, the preparation of media and reagents, and McCrady's table for the probable number of coliform organisms present in water.

The monograph includes a very concise and excellent statement of the interpretation of the laboratory results with which it is believed that most American workers would heartily agree.

JOHN F. NORTON

A General Textbook of Nursing
—By Evelyn C. Pearce. New York: Dutton, 1938. 888 pp. Price, \$3.75.

The author has again written from her broad personal experience in the care of the sick and in the teaching of nurses. While the book is entitled "A General Textbook of Nursing," it is planned as a comprehensive guide and it is just that. The volume is divided into six sections, presenting: (1) General and Special Nursing Measures and Procedures; (2) The Feeding of Adult Patients and Infants and Elementary Dietetics; (3) The Administration of Drugs and Medicines and Elementary Materia Medica, Poisons and Poisoning; (4) Medical Conditions and Diseases and their Treatment and Nursing; (5) Gynecological Conditions and Their Treatment and Nursing Care, Venereal Disease, A Short Account of Pregnancy; (6) Surgical Nursing and Elementary Surgical Technique.

While nursing procedures must vary according to the practices of the chiefs of staffs and hospital routines, Miss Pearce presents those phases of nursing care which are fundamental and prac-

tical and are particularly helpful to the inexperienced nurse in stating what she may expect to find, how the patients may react, and what is the nurse's responsibility.

The volume is richly illustrated with carefully marked photographs and drawings. The appendix gives some examples of the type of questions used in the final "state examinations" of the last few years and this, no doubt, indicates one of the chief uses for which the book was written. Throughout this very comprehensive presentation one has the conviction that the patient's comfort and recovery are always foremost in the nurse's mind and practice.

While this volume does not easily lend itself for use as a textbook, it is recommended as a reference book for schools of nursing libraries and for nurses in general practice who do not have good library facilities.

MARION G. HOWELL

A Textbook of Biochemistry—
By Roger J. Williams, Ph.D., D.Sc.
New York: Van Nostrand, 1938. 525 pp. Price, \$6.00.

Dr. Williams has written a short textbook of biochemistry, which presents the material in a manner somewhat different from most texts which have appeared recently. The order of presentation of the subject is obviously responsible for the novel features.

The book is divided into five parts. The first three sections concern respectively Biochemical Materials (largely colloid and organic chemistry, presented briefly), Tissue Composition and Food Composition. The last two which may be considered as the physiological applications, are respectively Bodily Mechanisms for Regulating Chemical Change, and Metabolism.

This is not a completely new method of approach. About 15 years ago, before medical students were advised to receive didactic instruction in elemen-

tary organic and physical chemistry in their pre-medical training, it was the favorite method of presenting the subject with some teachers. The duration of the course in biochemistry in medical schools was somewhat longer under those circumstances than it is now. At present it appears desirable to spend by far the larger proportion of time upon the physiological applications of chemistry.

The reviewer believes that the text, which is a worthy one, will have greater usefulness for courses in biochemistry designed for other than medical students.

D. L. DRABKIN

Nurses Handbook of Obstetrics
—By Louise Zabriskie, R.N. (5th ed.)
Philadelphia: Lippincott, 1937. 724 pp. Price, \$3.00.

The fifth edition of Miss Zabriskie's Handbook measures up to all expectations derived from the previous editions. It is difficult to conceive of a more comprehensive or complete guide for nurses in this important field. The selection and arrangement of material, the excellent illustrations, the handy glossary, references, and complete index, make it a valuable reference volume. Especial attention has been given to the photographic illustrations.

The public health implications of good obstetrics have not been overlooked. A chapter is devoted to antenatal care which includes not only the part played by the medical attendant but also the nurse's share in suitable instruction through personal conference and well organized classes for group instruction of prospective mothers and fathers. The chapter on Motherhood and Human Welfare is timely in view of the developments taking place in governmental extension of maternal and child hygiene. A brief chapter on the History of Obstetrics adds to the value of the Handbook.

RICHARD A. BOLT

Tuberculosis Clinic Manual—A Report of the Committee on Clinic Standards. By Herbert R. Edwards, M.D., Chairman. New York: National Tuberculosis Association, 1938. 57 pp. Price, \$.50.

In this small volume the Committee on Clinic Standards of the National Tuberculosis Association has put into concise form the component parts of desirable tuberculosis clinic practice as it is understood in progressive tuberculosis work in this country. Beginning with a historical introduction, the committee has defined, in the modern sense, the function and service of the clinic. It has discussed relationships with other agencies, responsibility, budgetary items, physical arrangement of the clinic quarters, the admission of patients, their records, standards of personnel, scope of medical services and clinic procedures, educational activities relating to clinic work, case finding methods, and standards of tuberculosis service.

Especially interesting are the short chapters on Responsible Agency, Relationships with Other Agencies, and Educational Activities. According to the committee "The voluntary agency has contributed much to the development of clinic services in this country. It is its responsibility to initiate and demonstrate clinic service in a community without such facilities, or even to supplement existing clinics by additional facilities in new areas. It is likewise the responsibility of the voluntary agency to bend every effort to cause the official agency to assume responsibility for such clinic service as soon as possible."

More extensive affiliation with medical schools is urged, it being pointed out that less than one-half of the 77 recognized medical schools in the United States in 1936 had an affiliation with a chest clinic.

The chapter on relationships with

other units of community health and welfare work discusses coöperation and correlation of clinic service with the private practitioner, the hospital and sanatorium, the relief agency, and the local nursing agency.

A comprehensive account is given on the management of clinic records and on the scope of medical services and clinic procedures. Diagnosis and supervision of the case have a prominent part in the description of service in the clinic.

The volume contains a bibliography of selected references on tuberculosis dispensaries. An appendix on the arrangement of clinic space includes two diagrams showing, respectively, the layout of a chest service in a health center building in New York City, and the layout of space in a store or loft adapted for clinic use.

This excellent manual may be used to great advantage in setting up a new clinic and in evaluating existing tuberculosis clinic services. Although the committee concludes that "such standards of practice as we may devise are at best suggestive and are bound to be altered by the varying circumstances met in an individual community," clinic chiefs and their coworkers will find this volume extremely useful. Witnessing the greater emphasis on the refinement of case finding methods in the tuberculosis program, tuberculosis workers everywhere should become acquainted with this comprehensive report.

BERNARD S. COLEMAN

The Road To Safety Series—By Horace Mann Buckley, Margaret L. White, Alice B. Adams, and Leslie R. Silvernale. New York: American Book Co., 1938.

The Series includes eight volumes, as follows: *Away We Go*, 56 pp., price \$.20; *Happy Times*, 137 pp., price \$.56; *In Storm and Sunshine*, 152 pp., price \$.64; *In Town and Country*, 216

pp., price \$.72; *Here and There*, 285 pp., price \$.72; *Around the Year*, 346 pp., price \$.76; *On Land and Water*, 357 pp., price \$.80; *Who Travels There?* 440 pp., price \$.88.

This is a series of 8 volumes dealing with the subject of safety. They range from a small paper covered booklet called "Away We Go" intended for the use of the child just entering school to the more imposing book of 440 pages for the older child and called "Who Travels There?" The vocabularies are graded of course to fit the various age levels; there are word lists and the illustrations are profuse and attractive.

Glancing over the various volumes one sees that about every conceivable situation which may menace life and limb is treated by means of illustrative stories (interesting ones, too or simple, well written articles. Several of the books contain a list of safety habits and attitudes with references to the pages illustrating them.

It would seem to this reviewer that every boy and girl might find in this series of books most everything needed about the dangers which beset even the wariest individual in this complicated life we must lead; and that the teacher will find here ample material for use in safety instruction.

MERRILL E. CHAMPION

Manual for Dental Technicians. Vulcanite—By J. A. Salzmann, D.D.S. New York: Pitman Publishing Corp., 1938. 346 pp. Price, \$4.00.

This is a valuable addition to the library for dental laboratory workers. The entire field of vulcanite denture construction is covered in a manner even more determined than that pursued in the prosthetic laboratories of dental schools.

The training of technicians has usually been by the apprentice method or in commercial schools of doubtful merit. While dental education has

been brought to a high level under the auspices of universities and the American Dental Association, the formal training of technicians has been neglected, hence this *Manual* would seem to fill a long felt want. It is interesting to note that courses of instruction in this field are now offered in vocational high schools of New York City.

There are a few errors, such as the transposition of figures 32 and 33 on page 26. Illustrations are numerous and helpful. The binding will stand a good deal of the rough treatment a laboratory manual must endure. The printing, arrangement of material, and make-up are of the best, and the book can be unreservedly recommended.

C. F. ELZEA

Office International D'Hygiene Publique, *Monthly Bulletin*, September, 1938.

This number is of great interest as again showing the increasing recognition of the constantly growing importance of the airplane as a possible carrier of infection.

It contains reports on the index of the *Aedes aegypti* in the various parts of Africa, a larval index in the centers of the Côte de l'Or, of Nigeria, and index of the *Aedes aegypti* in Kenya; also the distribution and incidence of the *Aedes aegypti* in the Anglo-egyptien Soudan, all by well known experts. There is a description of the sanitary provisions of the Aerodrome of Lokandu (Congo belge); also articles on the precautions taken in flights of airplanes from the standpoint of carrying yellow fever, and the automatic destruction of mosquitoes in airplanes in Africa.

From America we have articles on the organization of anti-yellow fever vaccination for the personnel of the airplane companies, and among the officers of the Public Health Service of the United States; immunization of

the operatives of the air lines against yellow fever; and a report on the hiding places of mosquitoes in airplanes.

All of these articles are useful and interesting. The article by Dr. Ross, the Chief Medical Officer of Health in the Department of Hygiene in the Union of South Africa, gives a complete exposition of the dangers of carrying yellow fever in South Africa by aerial navigation. One cannot but be amused at his statement that an "almost despairing" (*presque désespérée*) note is contained in a recent American report which held that it was almost certain that sooner or later infected passengers will reach by means of airplanes cities infected by *Aedes aegypti* in the southern part of the United States. It points out also that in the United States we no longer harbor the illusion of freeing the country entirely of the Aedes and are now devoting most attention to developing efficient means of ridding airplanes and airports of this mosquito.

MAZÛCK P. RAVENEL

Manual of Psychiatry and Mental Hygiene—By Aaron J. Rosanoff, M.D. (7th ed.) New York: Wiley, 1938. 1,091 pp. Price, \$7.50.

Dr. Rosanoff's book is rewritten and enlarged in an attempt to bring the manual up to date. It is a diligent work with generous excerpts from other authors and research men in the field—in fact sometimes too voluminous to preserve congruity. In presenting his subject, the author's view is one that regards psychiatry as psychobiological reactions of the individual to his environment. It is somewhat regrettable that this fact, together with his own work and interest, restricts his scope and confines his survey of literature mostly to those topics in which he himself is most interested or engaged. In such a complex and diversified field of psychiatry, this method limits the ob-

jective representation of facts known and aimed at, and impairs the thoroughness of the book, when names and works as divergent as those of Kretschmer and Jung are entirely omitted.

The chapter on Chaotic Sexuality is rather arbitrary with inclusion of some of the so-called schizophrenic psychoses. His division of schizophrenia into five etiological entities lacks justifiable foundation. The review of psychoanalysis is rather inadequate without depth and critical evaluation. The author's comments are mostly introductory, presenting Freud in the latter's own very abbreviated paragraphs, faced with excerpts of H. T. Hyman's solitary article, "The Value of Psychoanalysis as a Psychotherapeutic Procedure," published in the *Journal of the American Medical Association* in 1933.

"Today no individual worker can write a textbook of psychiatry on the basis of his own experience alone, no matter how extensive that experience might be," writes Dr. Rosanoff. He might have done better to invite as co-authors for individual chapters in his work some of those on whose works part of his manual is based, with him acting as a coördinator and editor, moulding the parts to shape and form to give to medical students a more lucid, impartial and adequate presentation of the state and problems of psychiatry.

RALPH S. BANAY

Maternal Care Complications—By F. L. Adair, M.D., Editor. Chicago: University of Chicago Press, 1938. 95 pp. Price, cloth \$1.00, paper \$.50.

Dr. Adair and his associates have brought together the essentials in the prevention of the most important complications of pregnancy; namely the toxemias of pregnancy, obstetric hemorrhages, and puerperal infection. The same technics advised for the prevention of these complications will undoubtedly reduce the incidence of the

lesser complications and diminish the morbidity as well as the mortality.

Each chapter is devoted to one of the complications and takes up systematically the etiology, pathology, symptoms, diagnosis, and treatment. The preventability in each instance is stressed. In referring to puerperal infection, the leading cause of puerperal mortality, the authors state: "the disease is almost completely preventable in properly conducted obstetric cases."

The authors recognize the value of suitable instruction of the prospective

mother as stated in the following: "Women must be properly instructed in personal care and must be taught to coöperate with and appreciate the doctor who is trying to give good antepartum and delivery care. Failure of proper lay coöperation is responsible for about 50 per cent of the preventable deaths among mothers."

While the authors recognize that the problem of reducing maternal mortality is complex, they have nevertheless indicated in this little volume the fundamental factors. RICHARD A. BOLT

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

In the Interest of Patience—Sanitarians who are tempted to be impatient with progress hereabouts will do well to look up this editorial account of the recent British milk bill, which treats pasteurization as if it were a dangerous experiment. Under the proposed law's "revolutionary" provisions, a local health authority *may* apply to the Minister of Health for an order which will permit him to require certain kinds of milk to be pasteurized, but there must be a public inquiry in each instance, and the loopholes that the law creates are big enough to allow all the milk carts in England to be driven through. Considering the reported sanitary condition of much of the English milk, the yeomanry of those tight little Isles seem in no danger of being deprived of their daily allotment of milk-carried germs.

ANON. Half-Hearted Pasteurization. *Lancet*. 2, 23:1304 (Dec. 3), 1938.

Important Committee Report—Here, along with what is known, are listed a few of the researches that should be carried on to give us some needed supplementary information about cancer. The amount of work to be done seems appalling.

ANON. Fundamental Cancer Research. *Pub. Health Rep.* 53, 48:2121 (Dec. 2), 1938.

About Mental Health—Two brief but stimulating papers upon a subject with which many health workers are woefully uninformed. As this reviewer is about the "woefullest," this annotation must be limited to the comment

that both seem well worth serious study.

HOULOSE, J. Contribution of Mental Hygiene to Education on the Elementary Level, and:

ANDERSON, F. N. Some Physiologic Concepts in Mental Hygiene. *J.A.M.A.* 111, 27:2447 (Dec. 31), 1938.

Idea's Germ—Here is a discussion device which is worthy of the consideration of public health educators and other health workers. The subtitles tell the significant story: "As it is—as it should be—on the elementary school level; as it is—as it should be—on the junior high school level; as it is—as it should be—on senior high school level."

BURKHARDT, C. H., *et al.* A Symposium on Physical Education. *J. Health & Phys. Ed.* 9, 10:608 (Dec.), 1938.

Summer Camps, Open Air Schools, etc.—How complete has been the change in our beliefs about tuberculosis during the last dozen years is told in a few paragraphs by this author, who proceeds to pull the shaky props from under some ineffective, but emotionally satisfying so-called antituberculosis projects that, the author hints, have handicapped the real work for a generation.

BUSH, C. Tuberculosis among Children of School Age. *J. School Health.* 8, 9:267 (Nov.), 1938.

May School Children Spread Tuberculosis?—Primary tuberculosis infection in children runs a course comparable to other acute infections though usually with unrecognized signs. About

10 per cent of cases of childhood infection will become ill with tuberculosis in adult years after reinfection. Children with first infection disease are a danger to their playmates for only the first few months, and then not seriously so, and special treatment is not needed for primary infection. Avoidance of contact is the only preventive.

HILL, L. F. Some Present Concepts of Tuberculosis among Infants and Children. *J. School Health.* 8, 9:249 (Nov.), 1938.

Modifying Measles—Convalescent serum given to measles patients after Koplick spots had appeared, but while in the preëruptive stage, definitely modified the disease in about 5 cases out of 6. Normal adult serum did not help. This therapy is recommended for debilitated children, those recently recovered from whooping cough, or those with a chronic disease.

KÖHN, J. L., *et al.* Treatment of Pre-eruptive Measles with Convalescent Serum. *J.A.M.A.* 111, 26:2361 (Dec. 24), 1938.

Why Scientific Answers Are Hard to Get—In New York City a group of 1,830 children of tuberculous parents have been kept under supervision, 880 of whom had received BCG. They were visited monthly by nurses and at frequent intervals by pediatricians, and an attempt was made to see that all received the same care. This paper has to do with the considerations that might affect the result, such as selection of cases for treatment and control, risk of heavy infection, race, reliability of diagnoses at death, etc. The results are not given in this paper, for the data are as yet insufficient for judgment.

LEVINE, M. L., *et al.* Immunization against Tuberculosis. *Am. Rev. Tuberc.* 37, 5:632 (Nov.), 1938.

Negro Diets—Health workers who write learned articles on good nutrition

will be interested in this account of what negroes in Harlem actually eat. Flour, rice, and potatoes are the usual fare. Fresh vegetables and fruit are rare, but milk is the food most neglected. It is regarded as a dainty.

OPPENHEIM, D. A. An Inquiry into the Dietary of a Negro Group. *Woman's Med. J.* 45, 12:360 (Dec.), 1938.

Facts about Germs You Probably Never Knew—Soap and water scrubbing removes germs from the skin at a constant logarithmic rate of roughly half in 6 minutes. Theoretically it would require $2\frac{1}{2}$ hours of continuous scrubbing to sterilize the skin. There is here a great deal of important information about transient and resident bacteria and other general facts that clinicians, public health nurses, and technicians especially should know.

PRICE, P. B. The Bacteriology of Normal Skin; A New Quantitative Test Applied to a Study of Bacterial Flora and the Disinfectant Action of Mechanical Cleansing. *J. Infect. Dis.* 63, 3:301 (Nov.-Dec.), 1938 (or) PRICE, P. B. New Studies in Surgical Bacteriology and Surgical Technic. *J.A.M.A.* 111, 22:1993 (Nov. 26), 1938.

Fear, Anxiety, Ignorance, and Childbirth—Why women worry during the antenatal period and what worry does to childbirth is told to a British Association of Midwife Supervisors. Mental hygiene is an important aspect of prenatal care.

READ, G. D. Antenatal Care of the Emotions. *Health Officer.* 3, 7-8:184 (Nov.-Dec.), 1938.

Pneumonia Prevention—Although treatment with the capsular substance of pneumococci will render the individual partially immune to infection, and although vaccination is a practical procedure in camps and institutions where men are in close contact, especially in the face of institutional epidemics, this method of protection

does not seem feasible as a public preventive measure, because the general incidence of the disease is so low. Treatment is justified for groups in which the risk is high. Education to urge precautions by those with colds, and efforts to prevent overcrowding are worth while public measures, for pneumonias are transmitted by carriers through close personal contact.

SMILLIE, W. G. The Prevention of Pneumonia. *New York State J. Med.* 38, 23: 1485 (Dec. 1), 1938.

Where To Go for Board Members
—Kiwanis clubs' support of community health projects are reviewed for the benefit of the (health administrator) "feller that needs a friend."

SUTTON, W. M. Public Health Programs in Kiwanis. *Pub. Health Nurs.* 30, 12:693 (Dec.), 1938.

Why Epidemics Spread—Old and favorite is the epidemiologic theory that disease outbreaks are produced by the increase in virulence of the causative organism, and that the epidemics end when most of the susceptibles are dead or recovered and the organism returns

to its former state of virulence. Some animal experiments are reported upon, which indicate that when susceptible races become infected, nearly all succumb, when immune types meet the same hazard, they are immune, and that in mixed populations, the severity of the epidemic depends upon the proportion of susceptibles, and with few exceptions they are the only ones involved. Mice are not men, but experimentally developed theories fit human epidemiology better than the older belief in an enhanced virulence of the germ. A stimulating paper.

WEBSTER, L. T. Inborn Resistance to Infectious Disease. *Sci. Month.* 48, 1:69 (Jan.), 1939.

Brass Tacks and Syphilis—Here is real meat. Some venereal disease social workers discuss the technics of dealing with venereal disease contacts and how to get them to be examined. A page of this is worth chapters of theorizing about venereal disease control.

ASSOCIATION NEWS

SIXTY-EIGHTH ANNUAL MEETING

Pittsburgh, Pa.

October 17-20, 1939

HEADQUARTERS — HOTEL WILLIAM PENN

OFFICERS AND EXECUTIVE COMMITTEE

PITTSBURGH ANNUAL MEETING

DR. I. Hope Alexander, Chairman of the Local Committee for the Sixty-eighth Annual Meeting of the Association in Pittsburgh, Pa., October 17-20, announces the following Committee appointments:

- I. Hope Alexander, M.D.....Chairman
Director, Department of Public Health
- W. W. McFarland, M.D.....Co-Chairman
Executive Director, General Health Council
- H. B. Meller, Sc.D.....Vice-Chairman
Bureau Chief, Bureau of Smoke Regulation
- H. F. Smyth, Jr., Ph.D.....Secretary
Mellon Institute of Industrial Research
- P. E. Marks, M.D.....Treasurer
Superintendent, Bureau of Infectious Diseases

Chairmen

- John R. Conover, M.D.....Finance Committee
Frick Building
- H. T. Price, M.D., President-elect.....Reception Committee
Allegheny County Medical Society
- L. W. Bass, Ph.D., Assistant Director.....Publicity and Radio Committee
Mellon Institute of Industrial Research
- H. J. Benz, M.D., Superintendent.....Meeting Rooms Committee
Bureau of Child Welfare
- Mrs. P. Burgin Digby, President.....Registration Committee
Pennsylvania Parent-Teacher Association
- L. M. Sandston, Superintendent-Engineer.....Scientific Trips Committee
Bureau of Sanitation
- S. R. Haythorn, M.D.....Entertainment Committee
Singer Memorial Laboratory, Allegheny
General Hospital
- Mrs. David B. Ludwig, President.....Ladies Entertainment Committee
Women's Auxiliary of Allegheny County
Medical Society
- C. Howard Marcy, M.D., Medical Director.....Membership and Attendance Committee
Tuberculosis League Hospital
- Howard Patton, Superintendent.....Transportation Committee
Bureau of Food Inspection

REPORT FROM THE COMMITTEE OF THE AMERICAN PUBLIC HEALTH ASSOCIATION APPOINTED TO
CONFER WITH THE INTERDEPARTMENTAL COMMITTEE TO COÖRDINATE HEALTH AND
WELFARE ACTIVITIES AND WITH OTHER AGENCIES, AS ADOPTED
BY THE GOVERNING COUNCIL.

THE committee met in Washington, D. C., on November 19, 1938, at the request of Miss Josephine Roche, Chairman of the Interdepartmental Committee, for an extended conference.

All members were present, including Abel Wolman, Dr. Eng., *Chairman*, J. N. Baker, M.D., Louis I. Dublin, Ph.D., A. T. McCormack, M.D., H. S. Mustard, M.D., J. L. Rice, M.D., F. J. Underwood, M.D., and, *ex-officio*, E. S. Godfrey, Jr., M.D., and Reginald M. Atwater, M.D.

The National Health Program was discussed from many angles but with particular reference to its bearing on the work of the public health profession and in accordance with the terms of reference of the Association Resolution dated October 27, 1938, to the end that the principles of the National Health Program may be translated promptly into effective action.

Without attempting to include all aspects of the matters discussed, the committee of the American Public Health Association presents the following statement of certain fundamental policies which it recommends to the Association for adoption as representing the considered judgment of this professional society of public health workers.

These recommendations, we believe, agree in most points substantially with the proposals of the Interdepartmental and Technical Committees on the federal-state relationships embodied in the National Health Program, and we agree that the primary federal function is to give financial and technical aid to the states for carrying out approved programs.

1. It is certainly theoretically desirable that a single state agency should be made administratively responsible for carrying out all the provisions of the National Health

Program which may be enacted into law. In recommending that this single agency should be the state department of health, we recognize that the present patterns in most states do not conform to this proposal, yet we note evidence that organized medicine and many public welfare officials share our opinion that at least ultimately the state health department should be the responsible agency. We believe that there are many affirmative reasons why the state health department is the best agency at the state level for this purpose. No agency will be able so readily or effectively as the health department to provide professionally qualified personnel and be so readily or effectively able to maintain high professional standards of medical care.

In recommending that the state health department should be the primary integrating and coördinating unit, we recognize that the counsel of qualified advisers from the medical, dental, nursing, hospital, and ancillary professions will be requisite, that adequate provisions for technical staffs and administrative expense will have to be made from the outset, and that increased funds for training purposes will be essential for successful performance. We have concluded further that, however reluctant medical health officers may be at present to take over these added responsibilities, a study of the alternative choices for such purposes will be determinative. This basic recommendation does not preclude a working arrangement in some states with existing machinery outside of the official health department which might function well through another channel, provided that the state health officer retains supervisory control over the broad plans and the general purposes of the funds which the state may receive. It is further recommended that in such plans due consideration will be given to the allocation of funds by a state department of health to the various substantial governmental jurisdictions within a state where population, extent of the special problems, or financial need justify.

We note that this proposal is in accord with the recommendation of the Interdepartmental Committee that this program should be developed around and be based upon existing preventive health services.

2. The committee reaffirms and reemphasizes the official declaration of the American Public Health Association that, in the initiation and development of the program, wide latitude should be given to the states in the definition of the population to be served, in the selection of the method of providing medical service, and in other important phases of the proposed program. We believe that similar latitude should be provided with regard to the method of raising funds in the states to accomplish approved objectives.
3. The committee finds itself in agreement with the recommendations in the National Health Program that the fundamental objectives involved here are, first, conservation of health and vitality and, second, reduction of the rôle of sickness as a cause of poverty and dependency. With this in mind, it supports the concept that Recommendations 1, 2, and 3 of the Interdepartmental Committee (the expansion of public health and maternal and child health services, the expansion of hospital, clinic, and other institutional facilities, and the provision of medical care for the medically needy) should have priority in initiation.
4. We believe that recent experience demonstrates that the Social Security Act provisions for aid to the states for health work provide a suitable framework for the expansion of preventive health services.
5. We submit that it is essential that any state program to be approved for federal aid should contain adequate provisions for the maintenance of high personnel standards and that payment of such federal aid to state agencies should be withheld when it is found that substandard services are being furnished. Similar policy should obtain with respect to state aid to local areas within a state. The appropriate federal administrative authorities should have power to establish minimum standards through rule and regulation after consultation with competent advisory professional bodies.
6. Careful study will be necessary to perfect administrative regulations to cover the details concerned with the provision of medical services, so as to assure a high level of quality. We believe that standards of medical practice should not be written into basic law. Federal aid should be conditioned on inclusion within the state plans of adequate safeguards for maintaining appropriate standards.
7. We believe that the extension and improvement of public health services in general throughout the country requires complete integration of health services of the federal government under one cabinet officer, preferably a Secretary of Health.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

William S. Bailey, 31 Glorieux St., Irvington, N. J., Health Officer
 Donald G. Barton, M.D., City Hall, Concord, N. H., Sanitary Officer, Dept. of Health
 Herman Baxt, M.D., Riker's Island, N. Y., Chief Medical Officer, Riker's Island Penitentiary and Hospital
 Joe M. Chisolm, M.D., Newport, Tenn., Cocke County Health Officer
 Richard R. Foster, Soule Bldg., New Orleans, La., Director, Dept. of Public Welfare
 Maurice Gore, M.D., 51 Fox St., Aurora, Ill., District State Health Superintendent
 Andrew R. Johnson, Jr., State Capitol Bldg., Baton Rouge, La., Director, State Hospital Board
 Edna C. Keefer, 26 Cherry St., Milford, Conn., Assistant to Health Officer
 Irvin Kerlan, M.D., Boyd County Health Dept., Ashland, Ky., Assistant Director

George E. Mueller, M.D., 1011 Lake St., Oak Park, Ill., Commissioner of Health
 Theodore R. Shrop, M.D., 1224 Washtenaw Ave., Ann Arbor, Mich., Chief, Division of Child Hygiene, Akron Health Dept. (Ohio) (Student at present)
 Charles A. Steurer, M.D., Central Drive, Port Washington, L. I., N. Y., Director, Division of Communicable Diseases, Nassau County Dept. of Health

Laboratory Section

Guy G. Frary, State Chemical Laboratory, Vermillion, S. D., State Chemist
 Ruth B. Glass, Capitol Bldg., Little Rock, Ark., Bacteriologist, State Board of Health
 Ervin W. Hopkins, Ph.D., Armour & Co., Chemical Research Lab., Chicago, Ill., Research Bacteriologist
 Richard J. Lebowich, M.D., 12 S. Park Drive, Gloversville, N. Y., Director, Fulton County Laboratory

Willard H. Rhodes, 933 Orizaba Ave., Long Beach, Calif., Student
Bennett Sallman, 510 N. State St., Ann Arbor, Mich., Student

Leonard O. Vose, 1017 State Capitol, Lincoln, Nebr., Director of Laboratories, State Dept. of Health

George I. Wallace, Ph.D., 362 Chemistry Bldg., Urbana, Ill., Asst. Professor of Bacteriology, University of Illinois

John N. Wilson, State Board of Health, Minneapolis, Minn., Assistant Biologist, Division of Sanitation

Vital Statistics Section

Erminie J. Cross, 231 E. 54 St., New York, N. Y., Statistical Secretary, Division of Health Studies, Commonwealth Fund

John D. B. Scott, Parliament Bldgs., Victoria, B. C., Canada, Statistician, Provincial Board of Health

Frances Sisselman, 570 Bradford St., Brooklyn, N. Y., Volunteer Worker, Henry Street Visiting Nurse Assn.

Irving V. Sollins, Ph.D., U. S. Public Health Service, Washington, D. C., Associate Statistician

Public Health Engineering Section

Henry M. Chick, District Bldg., Washington, D. C., Junior Public Health Engineer, Health Dept.

James J. Dillon, 335 State Office Bldg., Providence, R. I., Sanitary Engineer, State Dept. of Public Health

Albert M. Eldridge, Bartow County Health Dept., Cartersville, Ga., Sanitary Engineer

Samuel W. Fowler, 805 Rankin St., Greensboro, N. C., Public Health Trainee

Robert H. Gregory, Jr., Valley Health District, Luray, Va., Sanitarian, State Health Dept.

Carl D. Gross, State Health Dept., Springfield, Ill., Assistant Sanitary Engineer

John B. Harrington, 24 Washington St., S. Charleston, W. Va., Director, Division of Sanitary Engineering, State Dept. of Health

Floyd Osterhauadt, 704 West St., Carthage, N. Y., Health Inspector, Dept. of Health, New York, N. Y.

Food and Nutrition Section

Helmut C. Diehl, U. S. Frozen Pack Lab., Univ. of Wash. Campus, Seattle, Wash., Senior Chemist in Charge

James A. Heltzer, 551 Church St., Ann Arbor, Mich., Food Inspector, Health Dept.

Estelle Nesbitt, State Board of Health, Indianapolis, Ind., Director, Nutrition Division, Bureau of Maternal and Child Health

Howard C. Patton, 624 City-County Bldg., Pittsburgh, Pa., Superintendent, Bureau of Food Inspection, Dept. of Health
Rufus A. Roberts, D.V.M., 114 Greenville, LaGrange, Ga., Milk and Meat Inspector, Health Dept.

Industrial Hygiene Section

William Z. Fluck, B-1 State Office Bldg., Madison, Wis., Chemical Engineer, Industrial Hygiene Unit, State Board of Health

Child Hygiene Section

David B. Ast, D.D.S., State Office Bldg., Albany, N. Y., Assistant Director, Oral Hygiene, Division of Maternity, Infancy and Child Hygiene, State Dept. of Health
Charles S. Culotta, M.D., 388 Orange St., New Haven, Conn., Assistant Director, Child Health Conferences

E. Pearl Hannah, D.D.S., 543 Channing Ave., Palo Alto, Calif., Director, Dental Health for Public Schools

Marion C. Henderson, U. S. Dept. of Labor, Children's Bureau, Washington, D. C., Associate Statistician, Division of Statistical Research

Thomas R. O'Brien, M.D., 12 Baker St., Lynn, Mass., Director of School Health, Dept. of Health

William Schmidt, M.D., 411 E. 69 St., New York, N. Y., Director, Nutrition Study of High School Students, Coöperative Study of Cornell Medical College, U. S. Public Health Service, Department of Health and Milbank Memorial Fund

Edward J. Strick, M.D., D.Sc., 880 Forest Ave., Palo Alto, Calif., School Physician

Public Health Education Section

George P. Aitken, East Pike, Zanesville, O., Sanitarian, Muskingum County Board of Health

Alfred J. Agis, D.D.S., 33 W. 42 St., New York, N. Y., Director, Public Health Courses, Division of General Education, New York University

Lona B. Carroll, M.D., 3785 Clements Ave., Detroit, Mich., Public Health Trainee

Harold M. Cavins, 805 Sixth St., Charleston, Ill., Assistant Professor of Hygiene, Eastern Illinois State Teachers College

Robert P. Marsh, Ph.D., 100 Broadway, Gettysburg, Pa., Professor of Biology and Hygiene, Gettysburg College

Frank J. Mayer, 520 Cherry St., Ann Arbor, Mich., Student

Hazel K. Montrose, R.N., Jacksonville, Ill., City Health Nurse

N. P. Neilson, Ph.D., 1201-16 St., N. W., Washington, D. C., Executive Secretary,

American Association for Health, Physical Education and Recreation

Fred C. Spalding, 103 Sheyenne Blvd., Valley City, N. D., Director, Dept. of Physical and Health Education, State Teachers College

Public Health Nursing Section

Nora W. Camden, 100 W. 80 St., New York, N. Y., Supervisor, Queens Center, Henry Street Visiting Nurse Service

Ina M. Collins, R.N., Harrisonville, Mo., Public Health Nurse, State Board of Health
Margaret Donnen, County Health Dept., Camden, S. C., County Nurse

Olive H. Harr, 520 S. Forest, Ann Arbor, Mich., Student

Mary A. Johnson, 424 S. E. Harvard St., Minneapolis, Minn., Field Advisory Nurse, State Dept. of Health

Mabel Madden, 118 E. 91 St., New York, N. Y., Supervisor, Henry Street Visiting Nurse Service

Frances T. McDougal, R.N., Celery Ave., Box 62, Sanford, Fla., Seminole County Nurse
Aurora S. Nelson, Hill City, Kans., Public

Health Nurse, State Board of Health
Grace L. Westrope, R.N., 424 N. W. 6 St., Oklahoma City, Okla., Directing Field Nurse, Oklahoma Commission for Crippled Children

Mary L. Williams, R.N., 1317 Dreiss, Fort Worth, Tex., Tarrant County Public Health Nurse

Epidemiology Section

Malcolm H. Merrill, M.D., State Bldg., San Francisco, Calif., Chief, Bureau of Venereal Diseases, State Dept. of Public Health

Herman M. Soloway, M.D., 300½ S. Second St., Springfield, Ill., Venereal Disease Control Officer, State Dept. of Public Health

Unaffiliated

Meleta M. Harmon, 2700 W. Chicago Blvd., Detroit, Mich., Biology and Physiology Teacher, Central High School

David M. Heyman, 61 Broadway, New York, N. Y., Member, New York Board of Health

Milton C. Winternitz, M.D., 310 Cedar St., New Haven, Conn.

ANTHRAX REPORT AVAILABLE

AT the Kansas City Annual Meeting there was presented before the Industrial Hygiene Section a comprehensive report on "Anthrax in Industry," fully documented by Dr. Henry Field Smyth of Philadelphia.

In view of the limited scope of the Association Year Book, this report has been reproduced by the U. S. Public Health Service, and J. J. Bloomfield, Chairman of the Industrial Hygiene Section, announces that copies may be

obtained from the Division of Industrial Hygiene, National Institute of Health, Washington, D. C.

ROYAL SANITARY INSTITUTE

THE Royal Sanitary Institute of Great Britain will meet in Scarborough, England, July 3-8, 1939.

Fellows of the Association who expect to be in England during this period are requested to notify the Executive Secretary of the A.P.H.A., 50 West 50th Street, New York, N. Y.

Letter to the Editor

To the Editor:

In your November issue, on page 1356, is a notice of the paper by J. Yerushalmy entitled "Neonatal Mortality by Order of Birth and Age of Parents," which ends with the sentence: "Conclusion jumpers will find this article much to their liking." Being already acquainted with Mr. Yerushalmy's strictly scientific paper, which

is certainly of importance, I was dismayed to read this comment. May I urge your readers to consult the original and assure themselves that the author has sedulously avoided jumping to conclusions.

Very truly yours,

J. ROSSLYN EARP, DR.P.H.

December 30, 1938.

EMPLOYMENT SERVICE

The Employment Service will register persons qualified in the public health field without charge.

Replies to these advertisements, indicating clearly the key number on the envelope, should be addressed to the American Public Health Association, 50 W. 50 Street, New York, N. Y.

POSITIONS WANTED

HEALTH OFFICERS

Experienced physician, administrator, epidemiologist and teacher, now employed, with C.P.H. from Johns Hopkins, and 14 years' public health background, will consider position. Prefers epidemiology in city or state department. Excellent references. **A355**

Well qualified physician, with C.P.H. from Johns Hopkins; experienced as school physician and in college teaching, will consider city or county administrative position or teaching and student health service. **A383**

Physician, M.D., Class A medical school; M.P.H., Harvard School of Public Health; extensive experience in pediatrics and school medical services; also background of county health administration and teaching in medical school, will consider expanded opportunity in teaching or research. **A302**

Physician, M.D., Columbia, experienced as county health officer and superintendent of health, seeks position in public health administration or medical executive work. **A396**

Physician, M.D., Vanderbilt University; Dr.P.H., Johns Hopkins; experienced as epidemiologist, health officer and professor of preventive medicine, seeks position as administrator or epidemiologist. **A397**

Physician, 30 years of age, M.D., University of Illinois; C.P.H., University of California; experienced as instructor in medicine and director of state Division of Epidemiology, desires position in communicable disease control or administration. **A399**

Physician with M.P.H. from Harvard, experienced as epidemiologist and in county health administration, also in communicable diseases at state level, seeks responsible position. **A392**

Physician, M.D., McGill; C.P.H., Johns Hopkins; excellent background of communicable disease control and school health service, seeks position as epidemiologist or public health administrator. **A368**

HEALTH EDUCATION

Young woman, experienced teacher in health education, with M.S. in Public Health and Hygiene from University of Michigan, seeks position as health coordinator. **H398**

Young man, M.S.P.H., University of Michigan; at present college teacher of hygiene and physical education, and experienced in university medical service, desires position as executive in public or private health organization. **H357**

Young woman, M.A., Health Education, Teachers College, Columbia University; with splendid international experience, seeks position as director of health education. **H369**

LABORATORY

Bacteriologist and pathologist with wide administrative experience; Ph.D., Brown University; will consider leading position in his field. **L371**

Experienced laboratory director with background of dairy products manufacture and research in control methods; University of Wisconsin, M.S. and Ph.D., desires administrative position with food manufacturing or processing industry, or association with health department doing routine and research work in food control. **L381**

MISCELLANEOUS

Experienced teacher in bacteriology and public health, Ph.D., Cornell; now professor in Grade A medical school, will consider teaching, executive or administrative position. **M327**

Dentist, graduate of Temple University, with excellent postgraduate experience, desires position in administrative aspects of dental hygiene. **M352**

Public health engineer, B.S. in Sanitary Engineering from Massachusetts Institute of Technology, experienced in Massachusetts, Connecticut and Kentucky, seeks position as sanitary or public health engineer with health department. **E380**

NEWS FROM THE FIELD

WASHINGTON NEWS LETTER ON SOCIAL LEGISLATION

PROPOSED federal legislation of interest to public health officers is covered in the *Washington News Letter on Social Legislation* which began publication in January. It will report current developments regarding proposals

- To expand public health services
- To provide increased health protection for mothers and babies
- To construct and improve hospitals
- To provide medical care for needy persons
- To provide disability insurance
- To establish a federal or state system of health insurance

The *News Letter* seeks to present the best opinions obtainable as to the prospects and significance of these proposals. It concerns itself more with "off the record thinking" and "behind the scenes" situations than official statements. It also covers amendments suggested by state officials and their evaluations of amendments from other sources.

The *News Letter* will be issued bi-weekly while Congress is in session with special editions on matters of immediate interest at a cost of \$5 per subscription. For information, write Glen Leet, Editor, *Washington News Letter on Social Legislation*, 1733 Nineteenth Street, N. W., Washington, D. C.

NEW YORK PUBLIC HEALTH EDUCATION

A NEW 3 year plan for the extension of public health education work in the Health Department has been announced by Health Commissioner John L. Rice, of New York City.

Mr. Philip S. Broughton, who was connected with the recent nation-wide syphilis education campaign of the U. S. Public Health Service, has been appointed head of this project.

PUBLIC SCHOOL REPORT

EARLY in January there was submitted to the New York State Board of Regents a report on a 2 year inquiry on the public school system in New York State. A sub-committee on the School Health Program, under the Chairmanship of Professor C.-E. A. Winslow of Yale, reported that routine annual physical examinations had become so perfunctory that only glaring physical defects and common contagious diseases were usually detected. It was recommended that these examinations be abolished in favor of a new law to make thorough medical examinations compulsory for all children at only three intervals in their school careers.

In reporting that there were in existence many ill-lighted, ill-ventilated and otherwise unsanitary school buildings, the committee recommends the employment of a public health engineer under the Educational Department to counsel local school authorities on structural problems.

One portion of the report devoted to conditions in school buildings constitutes a vigorous attack on the system of ventilation now prescribed for all schools by state law, requiring all buildings to be fitted with mechanical ventilation systems capable of producing 30 cubic feet of fresh air a minute for each pupil. The committee holds that such systems are extravagantly costly, unnecessary, and even unhealthful. It was noted that the simple process of raising and lowering windows fitted with slanting boards to prevent drafts was far superior to the present plan.

In recommending that the first attempt to build a sane and thorough program of mental hygiene should originate in the state's schools, which are "the primary agency through which

modern concepts of human behavior can reach community thinking and practice," the committee reported that "teachers who would be considered by mental hygienists to have harmful effects upon children are found in abundance in the state schools."

In the section devoted to health services and examinations, the committee proposed that both physical tests and remedial work be left whenever possible to the family physicians of pupils. It held that medical inspectors now employed by schools were as a group not well qualified for their work and that the elimination of private doctors as now generally practised sapped the parents of responsibility for their children's welfare.

The practice of basing state aid to schools on attendance rather than on enrollment was reported by the committee to have caused numerous instances in which the health interests of children were sacrificed to the building up of financially profitable attendance records.

OHIO HEALTH COMMISSIONERS CONFERENCE

THE annual conference of Ohio health commissioners was recently called by Walter H. Hartung, M.D., State Director of Health. Among those who addressed the conference were: Allen W. Freeman, M.D., Professor of Public Health and Hygiene at Johns Hopkins University, Baltimore, and John A. Toomey, M.D., Associate Professor of Pediatrics, Western Reserve University School of Medicine, Cleveland.

Dr. Barney J. Hein, President of the Ohio State Medical Association, assured the conference that the medical profession supports whole-heartedly a public health program, and stressed the desirability of close and harmonious cooperation between official health workers and physicians.

U. S. HOUSING AUTHORITY ANNIVERSARY

NOVEMBER 1, 1938, marked the first anniversary of the U. S. Housing Authority.

Two hundred cities, with a total population of 33 million people, have housing authorities at the present time, and federal funds amounting to 575 million dollars have been earmarked for 142 cities.

NEW YORK CITY CONTROLS ADDITION OF CHEMICALS TO WATER SUPPLY

IN what may be the first instance in which a department of health has promulgated specific regulations concerning the addition of chemicals to a water supply for anticorrosion or anti-scaling purposes, the Board of Health of the City of New York on December 12 adopted regulations requiring a permit to be issued to persons who make a business of this work. The chemicals which may be added are limited and specified, and the amount which may be added is limited in terms of total hardness or total silica content of the water. The regulations also govern the mechanical device or apparatus constructed to regulate the chemical dosage, which must be approved by the Commissioner. There must also be provided protective means to prevent backflow or siphonage of treated water into the public water supply system. The regulations are effective April 1, 1939.

STATE LABORATORY DIRECTORS' TRANSACTIONS

THE Conference of State Laboratory Directors announces that mimeographed copies of the transactions of the Conference held at Kansas City on October 24, 1938, will shortly be available at 50 cents a copy. They may be secured from C. A. Perry, Sc.D., Secretary-Treasurer, 2411 N. Charles Street, Baltimore, Md.

NEW JERSEY HEALTH COMMITTEE

A SPECIAL committee, to be known as The New Jersey Committee on Health and Welfare, has been appointed by Governor A. Harry Moore.

This committee, the purpose of which is "to follow up and determine applications to the needs of New Jersey of certain of the considerations brought out at the Washington Conference in July," is under the chairmanship of Robert C. Clothier, LL.D., President of Rutgers University, New Brunswick, N. J.

AMERICAN CONGRESS ON OBSTETRICS

THE first American Congress devoted to a consideration of medical, nursing, and other problems associated with human reproduction will be held in the Municipal Auditorium, Cleveland, Ohio, from September 11 to 15, 1939. It will be designated as The American Congress on Obstetrics and Gynecology.

The promotion and sponsorship of the congress has been delegated to the American Committee on Maternal Welfare, Inc., which includes the following organizations in its membership:

- American Association of Obstetricians, Gynecologists and Abdominal Surgeons
- American College of Surgeons
- American Gynecological Society
- American Hospital Association
- American Nurses Association
- American Protestant Hospital Association
- American Medical Association Section on Obstetrics and Gynecology
- American Public Health Association
- Central Association of Obstetricians and Gynecologists
- Chicago Maternity Center
- Maternity Center Association of New York
- National Medical Association
- National League of Nursing
- National Organization for Public Health Nursing
- New England Obstetrical and Gynecological Society
- Pacific Coast Society of Obstetrics and Gynecology
- Southern Medical Association
- U. S. Bureau of the Census
- U. S. Children's Bureau
- U. S. Public Health Service

The purpose of this congress is to afford opportunities for discussing and publicizing the problems associated with human reproduction and the health of women and new-born babies.

The last International Congress of Obstetrics and Gynecology was held in Amsterdam, Holland, in May, 1938. Its success stimulated a desire to hold a subsequent one in five years in another European country.

MONTREAL ANTI-TUBERCULOSIS DRIVE

A TUBERCULOSIS Section in the Department of Health of Montreal, Que., has been authorized on the recommendation of Dr. Abelard Groulx, Director of the Department. The object of this new Section is to control, coördinate, and intensify the drive against tuberculosis in Montreal.

A meeting was organized by the Provincial Committee for the Prevention of Tuberculosis, in coöperation with the Department of Health, to launch the campaign. Among the speakers were Jean Gregoire, M.D., D.P.H., Deputy Minister of Health, who stated that there were at least 5,000 persons afflicted with tuberculosis at large in the Province, and stressed the necessity of an educational campaign; and A. Grant Fleming, M.D., D.P.H., Dean of the Faculty of Medicine, McGill University, who promised the support of McGill University in the present drive.

N.O.P.H.N. COMMITTEE OF FIVE

THE Executive Committee of the National Organization for Public Health Nursing, at its November meeting, appointed a Committee of Five to coöperate with the President's Interdepartmental Committee to Coördinate Health and Welfare Activities.

This committee consists of Grace Ross, Chairman, Mrs. Charles Brown, Elizabeth G. Fox, Livingston Farrand, M.D., and Dorothy Deming.

THE PRESIDENT'S MESSAGE ON HEALTH SECURITY

ON January 23, President Roosevelt transmitted to Congress a special message on health security specifically developing the subject mentioned in his annual message and commenting on the recommendations on national health prepared by the Interdepartmental Committee to Coördinate Health and Welfare Activities.

The report by Miss Josephine Roche as Chairman of the Interdepartmental Committee, attached to the President's message, points out that, though there can be no doubt that the general level of health in the United States is higher today than at any other time in the nation's history, nevertheless the evidence is equally clear that not all of the American people have shared adequately in this progress. In both rich states and in poor states there are large groups of persons for whom life is still as uncertain and as brief as if the scientific progress of the past half century had not occurred.

Specifically, the Interdepartmental Committee is now recommending to the President and to Congress four items as follows:

A. The expansion and strengthening of existing federal-state coöperative health programs under the Social Security Act through more nearly adequate grants-in-aid to the states and, through the states, to the localities.

B. Grants-in-aid to the states for the construction, enlargement, and modernization of hospitals and related facilities where these are nonexistent or inadequate but are needed, including the construction of health and diagnostic centers in areas, especially rural or sparsely populated, inaccessible to hospitals, including grants toward operating cost during the first years of such newly developed institu-

tions to assist the states and localities in taking over responsibilities.

C. That the federal government provide grants-in-aid to the states to assist in developing programs of medical care. It is conceded that a state program of medical care should take account of the needs of all persons for whom medical services are now inadequate besides focusing on the need of those persons for whom governmental agencies have already accepted some degree of responsibility. Committee studies show that attention should also be focused on the needs of the entire population, or at least on the needs of all low income groups. The committee is of the opinion that medical services are now inadequate among self-supporting people with small incomes, as well as among needy and medically needy persons. The committee believes that choice of the groups to be served, the scope of the services furnished, and the methods used to finance the program should be made by the states, subject to conformity of the state plans with standards necessary to insure effective use of the federal grants-in-aid.

To finance the program two sources of funds could be drawn upon by the states: (a) general taxation or special tax assessments, and (b) specific insurance contributions from the potential beneficiaries of an insurance system. The committee recommends grants-in-aid to states which develop programs using either method or a combination of the two, to implement programs of medical care. The committee believes it to be of fundamental importance that a medical care program developed by a state should be a unified program applicable to all groups to be served.

D. The development of social insurance to insure partial replacement of wages during temporary or permanent disability.

A complete report of the recommendations made by the President and the Interdepartmental Committee may be found in *Document 120*, 76th Congress, First Session, House of Representatives, which is obtainable from the Superintendent of Documents, Washington, D. C.

HARVARD SYMPOSIUM ON VIRUS AND RICKETTSIAL DISEASES

THE Faculty of the Harvard School of Public Health offers a short course of lectures, clinics, and demonstrations on the virus and rickettsial diseases, with special emphasis on their public health significance, at the School during the week of June 12-17, 1939.

Lectures on the etiology, epidemiology, and methods of control of these diseases, given by members of the Faculties and by former students of the Harvard School of Public Health and of the Harvard Medical School, will occupy five mornings. Special clinics and demonstrations will be given each afternoon. In some instances these demonstrations will be continued through the week, so that all the members of the symposium can attend. On the last morning, a panel discussion will be held on the three main topics presented in the symposium.

The fee for the course will be \$25.00, payable at any time up to June 12. Enrollment, however, should be arranged before June 1. Further information may be had by writing to the Secretary, School of Public Health, 55 Shattuck Street, Boston, Mass.

VITAMIN RESEARCH PRIZE OFFERED

TO promote interest in research on the water-soluble "B-complex" vitamins, Mead Johnson and Company, Evansville, Ind., has established an annual award of \$1,000 to be presented over a period of five years, through the American Institute of Nutrition. A committee of members of the Institute will select the recipient, and the presentation will be made a feature of its annual spring meeting.

The award will be given to the laboratory (non-clinical) or clinical research worker in the United States or Canada who in the opinion of the judges has published during the previous calendar year the most meritorious report deal-

ing with the B-complex vitamins. If circumstances and justice dictate, the prize may be divided among two or more persons, or it may be given to a worker for valuable contributions over an extended period, but not necessarily representative of a given year.

Nominations may be sent at any time to: Leonard A. Maynard, Ph.D., Laboratory of Animal Nutrition, Cornell University, Ithaca, N. Y. To be considered for the award at any given spring meeting, the nomination must be received by January 15.

PERSONALS

Central States

DR. MARY ALLEN, of Cleveland, Ohio, was recently appointed Staff Physician of the Bureau of Maternal and Child Health of the Wisconsin State Department of Health. She succeeds DR. RUTH A. B. BENNETT, of Galveston, Tex., who resigned.

LLOYD L. ARNOLD, A.M., M.D.,* Professor of Bacteriology and Public Health at the University of Illinois College of Medicine, and Director of the Chicago laboratories of the State Department of Health, has been appointed a member of the Chicago Board of Health, succeeding LOUIS E. SCHMIDT, M.D.,* resigned.

DR. FRANCIS A. DULAK, a member of the staff since 1934, has been appointed Secretary of the Chicago, Ill., Board of Health, following the resignation of LOUIS E. SCHMIDT, M.D.*

G. HOWARD GOWEN, M.D., Ph.D.,* has resigned as Director of the Champaign-Urbana Public Health District, Champaign, Ill., to accept the position of Chief Medical Officer of the Chicago Board of Health, effective in December, 1938.

HAROLD A. WHITTAKER,* of Minneapolis, Director of the Division of

* Fellow A.P.H.A.

† Member A.P.H.A.

Sanitation, Minnesota State Department of Health, and a member of the Committee on the Hygiene of Housing of the A.P.H.A., returned in January from Geneva, Switzerland, where he attended a meeting of the Committee on Housing of the League of Nations which met in December.

Eastern States

DR. HERBERT M. GODDARD, of Philadelphia, Pa., has been appointed Assistant Director of Public Health, to succeed the late DR. ALFRED F. ALLMAN.

ROBERT M. HURSH, M.D., has been appointed Health Officer of Harrisburg, Pa., succeeding the late JOHN M. J. RAUNICK, M.D.,* who had served since 1912.

H. G. STEVENS, M.D., has been appointed Health Officer of Sherman, Conn., succeeding R. W. MUNCH.

Southern States

NORMAN G. ANGSTADT, M.D.,† of New Martinsville, W. Va., has been appointed Health Officer of Wetzel County, to succeed DR. JOHN B. HOZIER, Acting Health Officer during the past year.

DR. WILLIAM A. BEVACQUA, of Charleston, W. Va., has been appointed Health Officer of Parkersburg and Wood County, to succeed ARTHUR D. KNOTT, M.D.,* of Parkersburg, resigned.

DR. TERRY BIRD, of Tavares, Fla., has been appointed in charge of the newly created Lake County Health Unit.

FREDERICK E. DARGATZ, M.D.,† formerly of Kinsley, Kans., has been appointed Director of the health unit of Ardmore, Okla., to succeed DR. RICHARD M. PARISH.

DR. MARTIN L. FULLER has been appointed City Health Officer of

Amarillo, Tex., recently separated from the Potter County Health Unit. EARLE C. GATES, M.D., has been appointed Health Officer of the Washington-Bristol Health Department, with headquarters in Bristol, Va., He succeeds MACK I. SHANHOLTZ, M.D.,† who resigned to accept a position in Oklahoma.

DR. HENRY J. GERMANY, of Waco, was recently appointed City Health Officer of Waco, Tex., succeeding the late DR. GEORGE M. LIDDELL, who had resigned October 1.

ELINOR D. GREGG,* Director of Nursing of the U. S. Indian Service, Washington, D. C., has resigned, effective January 1.

J. H. LEVAN, C.E.,† is in charge of the *Aedes aegypti* Control Unit, U. S. Public Health Service—with headquarters at the Miami Beach Quarantine Station—which is engaged in a *Stegomyia* survey and control at Key West, Fla., in coöperation with local authorities.

THOMAS PARRAN, M.D.,* Surgeon General of the U. S. Public Health Service, Washington, was awarded the William Freeman Snow Medal for outstanding service to social hygiene, at the 26th Annual Meeting of the American Social Hygiene Association in Washington, D. C., on February 1. According to the announcement, "Dr. Parran has been chosen for the award because of his great contribution to the health and happiness of the American people through his persistent efforts against syphilis and the conditions which favor its spread."

PAUL S. PARRINO, M.D.,† has been appointed Health Officer of Franklin, La., to succeed FORD S. WILLIAMS, M.D.

DR. GEORGE T. ROYSE has been appointed County Health Officer of

* Fellow A.P.H.A.

† Member A.P.H.A.

Potter County, Tex., with headquarters at Amarillo.

COL. JOSEPH F. SILER,† Director of the Army Medical School, Washington, D. C., has been awarded the Dr. George M. Kober Lectureship in recognition of his work in medical research.

FORD S. WILLIAMS, M.D.,‡ formerly Medical Director of St. Mary Parish Health Department, Franklin, La., has been appointed Louisiana State Director of Venereal Disease Control by the State Board of Health.

DR. REED WOLFE, of Sulphur, Okla., has been appointed Health Superintendent of Choctaw County.

Western States

J. WARREN BELL, M.D., PH.D.,* formerly Director of the Division of Maternal and Child Health of the Nebraska State Department of Health, has been appointed Medical Director of the National Society for the Prevention of Blindness, New York, N. Y.

DR. WILLIAM A. CLARKE has been appointed Health Officer of Holtville, Calif., to succeed DR. HARRY B. GRAESER.

CHARLES C. GANS, M.D.,‡ of Redwood City, Calif., Health Officer of the County of San Mateo, is now also Health Officer of San Mateo City, which has recently come under the county's jurisdiction. DR. JAMES A. WARBURTON has served for many years as Health Officer of the City of San Mateo.

Canada

ELIZABETH L. SMELLIE, R.N.,* Chief Superintendent of the Victorian Order of Nurses for Canada, Ottawa, Ont., was awarded the Mary Agnes Snively Memorial Medal by the Canadian Nurses Association in recognition of Miss Smellie's contribution to Canadian nurses and nursing.

Cuba

DR. DOMINGO F. RAMOS,* Secretary of Defense and Director of Public Health of Cuba, has been elected an honorary member of the American Club. This distinction has rarely been accorded either American or Cuban citizens since the Club was founded 37 years ago. The *Havana Post* reports that the Club's Board of Governor's, which elected Dr. Ramos unanimously, took into account the fact that he is regarded throughout Latin-America as the exemplification of the highest standard of ethics in his profession.

Deaths

V. H. BASSETT, M.D.,* City-County Health Officer of Savannah, Ga., died November 3, 1938.

W. J. V. DEACON, M.D.,* of East Lansing, Mich., died December 20, at the age of 70. He had been a member of the staff of the Michigan Department of Health since 1919, coming to Lansing from the Kansas State Health Department, where he was State Registrar. He had been a member of the A.P.H.A. since 1912 and was a Charter Fellow. He was Vice-Chairman of the Vital Statistics Section in 1917-1918, and Chairman in 1924.

HANS CHRISTIAN JOACHIM GRAM, whose name is known all over the world as the discoverer of the system of bacteriological staining which bears his name, died November 14, 1938. He was born in 1853, in Denmark. His professional career covered several fields. He was a laboratory worker, a pharmacologist, and head of a hospital service.

LOUIS ISRAEL HARRIS, M.D., Health Commissioner of New York, 1926-1928, died January 6, at the age of 56. He became a member of the

* Fellow A.P.H.A.

† Member A.P.H.A.

A.P.H.A. in 1915, and a Charter Fellow in 1922. He was Vice-President in 1930, a member of the Governing Council 1922-1925, and served on the Executive Board in 1929.

WILLIAM C. HUNSICKER, M.D.,† Director of the Department of Public Health of Philadelphia, Pa. and a former State Senator, died January 10, at the age of 65. Dr. Hunsicker was Professor of Urology at the Hahnemann Medical College for many years.

† Member A.P.H.A.

JOSEPH C. SAILLE, M.D.,† for 32 years Health Officer of Bloomfield, N. J., and former President of the New Jersey State Health Officers Association, died January 12, at the age of 76.

WILLIAM R. TRACEY,* Chief of Vital Statistics, Dominion Bureau of Statistics, Ottawa, Canada, died January 9. He had been a member of the A.P.H.A. from 1935, and a Fellow from 1937; and was recently Vice-Chairman of the Vital Statistics Section.

CONFERENCES AND DATES

American Association for Social Security. New York, N. Y. April 7-8.

Diphtheria Immunization With Fluid Toxoid and Alum Precipitated Toxoid*

Preliminary Report

VLADIMIR K. VOLK, M.D., D.P.H., F.A.P.H.A., AND
WILLIAM EDWARD BUNNEY, PH.D., F.A.P.H.A.†

THE studies were planned to investigate the height and duration of the antitoxic immunity following immunization with fluid and alum precipitated diphtheria toxoid. Conflicting reports^{1, 2, 3, 4} on the comparative values of these two antigens made such a study seem important. We present a comparison of results from 1 dose of alum precipitated toxoid and 2 doses of fluid toxoid at 4 months, 1 year, and 2 years after injection; and a comparison of 2 doses of alum precipitated toxoid and 3 doses of fluid toxoid at 4 months after injection.

METHODS

The study is being carried out on free-living children primarily from rural

schools in Saginaw County, a county of about 1,110 square miles. A total of 1,800 children are included in the report. The following procedures were used in immunization:

1. 1 injection of fluid toxoid
2. 2 injections of fluid toxoid (2 weeks apart)
3. 2 injections of fluid toxoid (3 weeks apart)
4. 3 injections of fluid toxoid (3 weeks apart)
5. 1 injection of alum precipitated toxoid
6. 2 injections of alum precipitated toxoid (3 weeks apart)

In addition a group of unselected children who received no injection were blood titrated at the end of 4 and 12 months. In a strictly controlled group alternate children in each school received the 2 immunizing agents. In this way 2 doses of fluid and 1 of alum precipitated toxoid were compared in some schools, and 3 doses of fluid compared with 2 doses of alum precipitated toxoid in other schools. The results from these controlled groups are analyzed separately as well as combined

* These studies are being carried out under a grant from the American Public Health Association and the U. S. Public Health Service, in cooperation with the Saginaw County Health Department and the Michigan State Department of Health. Read before the Joint Session of the Laboratory and Epidemiology Sections of the American Public Health Association at its Sixty-seventh Annual Meeting in Kansas City, Mo., on October 27, 1938.

† With the technical assistance of Anita Leavitt, Ann Sonderman and Louise Hagaman.

with the results obtained when alternate schools received the 2 immunizing agents. The schools included in the investigation number 110.

It was decided to follow the immunity response by blood titrations only. The Schick test was not used because of the well known fact that the Schick test itself has an antigenic effect, especially when given to a child already having antitoxin circulating in its blood. Therefore, before giving immunizing treatment, 4-5 ml. of blood were taken from the children. The children were bled again in 4 months and 12 months, and will be bled every 12 months thereafter for the duration of the study so that not only the height of the antitoxin level but the relative permanence of that level will be determined. A 1 ml. injection of the fluid or alum precipitated toxoid was given subcutaneously in the upper arm. Whenever a second or a third injection was given, a 3 weeks' interval usually elapsed between the injections. A small group was given injections with a 2 weeks' interval.

The toxoid used was obtained from

a commercial firm by Dr. W. T. Harrison of the National Institute of Health. It was felt advisable to use such a product because it was widely available. The alum precipitated toxoid was prepared from the fluid toxoid used in the study. This was felt to be important because of the possibility that two different preparations of toxoid might vary in some intrinsic antigenic efficacy for which we have no method of determination. The preparation used had a high average potency. The National Institute of Health tests showed 20 L_t /ml., and the alum precipitated toxoid to stimulate production of an average of 2-4 units of antitoxin in guinea pigs in the National Institute of Health control tests for alum precipitated toxoid. On the re-resolution of the alum precipitated toxoid it was likewise found to have 20 L_t /ml.

RESULTS

Of the 1,800 children, 358, or 20 per cent, had titratable antitoxin (.001 unit or more per ml.) in their circulating blood at the time of the first injection

of antigen. The majority showed a marked rise in antitoxin content following the injections and of course are not included in the results analyzed in this report. This leaves 1,442 children with less than .001 unit of antitoxin at the time of the first injection, and this paper is concerned with a comparison of the antitoxin levels in these children following the different methods of immunization described.

Table I shows the age distribution of the 1,800 children. Of these, 374 or about 28 per cent, are of preschool age; 1,252, or 70 per cent, are between the ages of 6 and 10; and 174, or 9.2 per cent are between the ages of 11 and 15. Included are 201 cases from Genesee County, studied in coöperation with Dr. L. V. Burkett, Genesee County Health Commissioner, Flint, Mich.

As stated, part of the children were in a strictly controlled group with each alternate child receiving different immunizing procedures. These results are entered in Table II under "controlled." For the rest of the children the two immunizing agents were given in alternate schools. This group is classified as "uncontrolled" in Table II. It is evident that the results in the two groups are strictly comparable. The number of children developing .001 unit or more of antitoxin is made the basis of analysis in this table. The

two groups proved equally comparable when .01 or 0.1 unit was the basis of comparison. To conserve space, analyses at these levels are not included here. Since the "controlled" and "uncontrolled" groups are comparable, the results from the two groups are pooled in the remainder of the report to simplify presentation.

Table III shows the comparison of the antitoxin response of the children to different immunizing procedures. Of the children who received no immunizing injection 11 per cent developed antitoxin at the end of 4 or 12 months. This is rather high for a community with the low carrier rate (see later) we have found in Saginaw County. However, all of these children merely changed from less than .001 to .001 unit and may very well represent only the degree of unreliability of the titrations at this low level. The group that received one injection of fluid toxoid responded very poorly by the end of 10 days and the antitoxic response was still low at the end of 4 and 12 months.

The group that received one injection of alum precipitated toxoid also responded very poorly at the end of 10 days, having 27 per cent with .001 or more units of antitoxin.

One hundred and sixty children who received 2 injections of fluid toxoid at 3 week intervals showed an antitoxic

response in 64 per cent at the end of 4 months. This percentage was reduced to 60 per cent at the end of 12 months, and 45 per cent at the end of 18 months.

For comparison the antitoxic response may be noted when the interval was reduced to 2 weeks. The figures indicate that 85 per cent showed a response at the end of 4 months, 60 per cent at the end of 12 months, and even 46 per cent at the end of 24 months. The difference between these and the 3 week interval results is not statistically significant with the numbers concerned.

Better response was observed in the group of 352 children who received one injection of alum precipitated toxoid.

In this group 93 per cent showed an increase in antibody at the end of 4 months. As time went on some loss of antitoxin was noticed, although 75.7 per cent still maintained the increased antitoxin level at the end of 2 years. The difference between these and the 2 fluid toxoid injection results is statistically significant and can be considered as proved under the conditions of this study.

Of 162 children who received 3 injections of fluid toxoid at 3 week intervals, 98 per cent showed an increase in circulating antitoxin at the end of 4 months, and 96 per cent at the end of 12 months.

Of 148 children who received 2 in-

tions of alum precipitated toxoid and who were followed for a period of 4 months only, 100 per cent showed an antitoxin response within 4 months. Twelve months have not elapsed since the last injection.

Table IV shows the antitoxin response at the end of 10 days after a single injection of either fluid or alum precipitated toxoid. Those receiving fluid toxoid who did not have titratable antitoxin to start with showed an increase in 21 per cent only, although it can be seen from the table that some show a surprisingly high rise in antitoxin level.

Groups which received alum precipitated toxoid injections showed an increase in antitoxin in 28 per cent of the children at the end of 10 days.

A group of children who had more than .001 unit of antitoxin demonstrated prompt response to antigenic stimulation. This can be seen in Table V. These results are interesting because of the frequent questions as to the advisability of giving immunizing injections after exposure. In cases of exposure to diphtheria it might be a very desirable procedure to give some kind of antigen to children. Of the 4 chil-

dren who failed to show an increase in antitoxin, 3 had a titer of less than .002 unit and 1 a titer of .004 unit per ml. before injection. Whether these represent a negative phase or the unreliability of titrations at this low level of antitoxin cannot be said. This phase of the problem is receiving further detailed study.

Table VI shows the actual antitoxin levels achieved at different intervals following the several immunizing procedures. It is evident that a procedure which causes more children to develop an appreciable antitoxin titer also produces more with antitoxin in higher concentrations.

In our series of 360 children receiving 2 injections of alum precipitated toxoid, we observed no reactions indicative of sensitivity following the second injection. It is indeed suggestive that 2 injections of alum precipitated toxoid produce the highest antitoxin level of all procedures tried. As we started this group in the spring, we are not in

a position to present observations for longer than 4 months.

Table VII shows a comparison of response in preschool and school children receiving one injection of alum precipitated toxoid and fluid toxoid. There may be a tendency for the preschool children to show a better response to the immunizing treatment than the school children but the figures are not large enough for the differences to be significant. Further work is being done on this point.

In addition to following the immunity response, a continual diphtheria carrier survey is being carried on in the schools. Throat cultures are taken from all the school children irrespective of whether they have received toxoid or not. This is felt to be essential for the intelligent evaluation of the immunizing results obtained because one might expect a much higher antitoxin response in a locality with a high carrier rate of virulent diphtheria organisms and a lower response in a locality where

1938	9,188	.37	9	.1	21	.23	5	.05
Total	19,346	.42	31	.16	38	.2	14	.07

exposure to virulent diphtheria organisms is a rarity.⁵ An attempt is being made to take throat cultures at regular intervals during the months of highest morbidity rate. Every positive culture is now being examined for virulence and the child is tested repeatedly as long as it remains a carrier. Of the 19,346 throat cultures taken 83 were found KL positive, of whom 31 were found virulent (see Table VIII). The antitoxin level of all diphtheria carriers is determined at frequent intervals in order to evaluate influences of harbored diphtheria bacilli on the immunity response of the child.

The diphtheria carrier survey covered 119 schools, and 7,347 children were cultured.

DISCUSSION

This paper is concerned solely with the antitoxin response to different immunizing procedures. No attempt is made to prove that any one procedure is the procedure of choice for routine immunization against diphtheria, and for two reasons: (1) The ultimate basis for the evaluation of any immunization method is whether or not it protects against diphtheria, and not necessarily whether or not it confers Schick negativity or raises the antitoxin level to any definite point; (2) It is entirely possible that a procedure which results in a lower level of antitoxin than some other may still be the method of choice from the public health standpoint. That is, it might be less expensive, be easier to administer, and confer a high enough percentage of immunity to be the most efficient use of the public health dollar in prevention of diphtheria. It may be a question of striking a balance between the conferring of the highest possible immunity to the individual on the one hand, and the reduction of diphtheria by conferring a lower but sufficient level of immunity to the community as a whole on the other.

The fact that no abscesses or severe reactions have followed the 2 injections of alum precipitated toxoid augurs well for the future of this method of immunization.

In most studies of a diphtheria immunizing procedure the Schick test is used. On the other hand, in much of the routine immunization a pre-Schick test is not used and probably will be used less and less in the future as pre-school immunization increases. Thus, since the Schick test may possibly have an antigenic effect, it becomes important from the practical point of view to evaluate diphtheria immunization in the absence of the Schick test, as done in this study.

FitzGerald, et al.⁶ report a better antitoxin response to 3 doses of fluid toxoid than to 2 injections of alum precipitated toxoid, just the opposite of our results. There is no significant difference between their results and ours with 2 doses of alum precipitated toxoid. There is a significant difference between their results and ours with 3 injections of fluid toxoid, our results being definitely lower than theirs. Perhaps this is due to a difference in the toxoids used, but it may be unsound to compare their fluid toxoid results with ours or with their own alum precipitated toxoid results since their 3 dose fluid toxoid results are based on those children who were originally Schick positive and not on the basis of those who had originally no titratable antitoxin. In other words, in contrast to their other groups (and to ours) their 3 dose fluid toxoid group had the benefit of the stimulus from a Schick test, and also might perhaps have contained some children who gave positive Schick tests but had titratable antitoxin below the .01 unit level and so would give marked response to any immunizing procedure. On the other hand, Fraser and Halpern³ in a study of 32 children observed a similar high response to 3 injections of

fluid toxoid. Here again some of the children received a pre-Schick test but all were titrated for antitoxin content before injection making the conditions more comparable to ours. Perhaps these latter results do point to some undetermined difference in the fluid toxoids used. It is conceivable that different technics or environments influence the results but one might expect these factors also to effect a difference in the alum precipitated toxoid results.

SUMMARY

The antitoxin response of children to several diphtheria immunization procedures has been determined. In the increasing order of the response they

induce, they are, under the conditions of our study: 1 dose fluid toxoid, 2 doses of fluid toxoid at 3 week interval, 1 dose of alum precipitated toxoid, 3 doses of fluid toxoid at 3 week interval, and 2 doses of alum precipitated toxoid at 3 week interval.

Tribute to a Public-Spirited Physician

Legend on a Memorial Statue, St. Paul's Cathedral, London, England

William Babington, M.D., F.R.S., Fellow of the Royal College of Physicians, born May 21, 1756, died April 29, 1833. "Eminently distinguished for science, beloved for the simplicity of his manners and the benevolence of his heart, respected for his inflexible integrity and his pure and unaffected piety. In all the relations of his professional life he was sagacious, candid, diligent and humane; firm in his purpose, gentle in execution; justly confident

in his own judgment, yet generously open to the opinion of others. Liberal and indulgent to his brethren but ever mindful of his duty to the public.

"To record their admiration of so rare a union of intellectual excellence and moral worth and to extend to future generations the salutary influence which his living example can no longer diffuse, this monument has been erected by the public subscription of his contemporaries. A.D. 1837."

Asbestosis*

R. R. SAYERS, M.D., F.A.P.H.A., AND
W. C. DREESSEN, M.D.

*Senior Surgeon, and Passed Assistant Surgeon, U. S. Public
Health Service, Washington, D. C.*

ASBESTOS is well adapted for use as a textile material because of its fibrous nature. On account of this, as well as its non-combustible and excellent insulating properties, it has come to be used in ever increasing quantities during the past 20 years. Hence, it is not surprising that Gloyne and Merewether¹ should refer to pulmonary asbestosis as a "modern disease."

The first record of a case of asbestosis seems to have been made by Montague Murray in 1900. The first complete description of the disease and of the "curious bodies" seen in lung tissue and sputum appeared in 1927 when Cooke² and McDonald³ reported 2 cases of asbestosis and listed their reasons for believing that asbestosis bodies originate from asbestos fibers that reach the lungs. Their papers aroused general interest in the subject and numerous others appeared soon afterward. Hoffman⁴ appears to have been the first American to call attention to the magnitude of the asbestosis problem. In 1918 he reported that 13 deaths from asbestosis had occurred among asbestos textile workers, and about the same time Pancoast, Miller, and Landis⁵ reported on 17 cases of asbestosis. Mills's⁶ paper was the first

pathological report on asbestosis published in the United States, and in the same year, 1930, Lynch and Smith⁷ reported on asbestosis bodies found in the sputum of asbestos workers.

The Public Health Service was requested by the State Board of Health and the Industrial Commission (Administrator of the Workmen's Compensation Act) of North Carolina to assist them in making an engineering and medical study of the health hazards in the asbestos textile industry of that state. The objectives of this study were:

1. To make a medical study of the effects of long-continued inhalation of asbestos dust on the human body.
2. To identify the manufacturing processes that create dust, and to recommend practices for reducing the dust exposure of workers.
3. To find out what concentrations of asbestos dust can be tolerated without injury. It is the purpose of this paper to review briefly the principal findings of this study.⁸

ENGINEERING FINDINGS

The main asbestos raw material used for textiles is Canadian chrysotile, which is a hydrated magnesium silicate containing no quartz.

The textile manipulations of asbestos are very similar to the production of cotton or woolen goods. The crude fiber is sent first to the preparation department, then, in the order named, to the carding machines, spinning frames, winding bobbins, twisting ma-

chines, spooling frames, and finally to the looms and miscellaneous fabricating devices.

In all, 242 dust counts were made in estimating the exposure of these asbestos workers. Only summary engineering findings, or dust concentrations as they relate to medical findings, will be discussed. Summarized results of dust concentrations under controlled and uncontrolled conditions appear in Table I. It will be noted that 74.3 million particles per cubic foot (m.p.p.c.f.) is the maximum concentration of dust encountered. Even this maximum figure is much lower than is frequently encountered in other siliceous trades where it has not been uncommon to encounter maximum dust concentrations of 1,000 m.p.p.c.f.

The dust in asbestos plants is made

up of particulate matter and fibers. The median size in microns of particulate matter ranged from 1.85 to 2.40. Particles were smallest in the carding and preparation processes, and largest in weaving. The median length of fibers in microns ranged from 7 to 16.3. As might be expected, the longest (400 μ) were noted in case of weaving and the shortest in preparation.

Weaving (tape)	2.40	1.64	0	3	11	24	14	12	7	13	7	5	6	100

The significance of dust concentrations and physical characteristics of these air contaminants will be referred to in the course of subsequent discussion.

The workers who were found particularly liable to develop severe forms of asbestosis were the willowers, pickers, carders, mule and ring spinners, twisters, and cloth weavers. Their exposure was found to be as follows:

	Dust concentration MPPCF
Willowers	11.1-36.0
Pickers	34.3-74.3
Carders and tenders	29.1
Mule spinners	2.6- 7.9
Ring spinners	3.2- 8.3
Twisters	3.2-13.2
Cloth weavers	
Dry	4.7-49.7
Wet	4.7-11.1

MEDICAL FINDINGS

Medical examinations were made of 541 men and women representing practically all the employees at the time of study. Five-sixths of them were native born Americans of Anglo-Saxon stock and the remainder were Negro males. The three factories studied had been in operation from 6 to 16 years. About 15 months before the study, approximately 150 workers were replaced by new ones with little or no asbestos experience. As a consequence, there was an abnormally large percentage of workers with less than 5 years' employment in the asbestos textile industry and an abnormally small percentage who had worked 10 years or more in the industry. More than 200 had worked at comparable occupations in cotton or woolen textile plants, but exposures to pneumoconiosis producing dusts were inconsequential.

Characteristics of asbestosis—Pulmonary asbestosis was the principal physical defect found on examining the 541 persons. This disease, a form of pneumoconiosis caused by long continued inhalation of asbestos dust, is

characterized pathologically by diffuse interstitial pulmonary fibrosis and the presence of asbestosis bodies in the lungs. Clinically, the chief symptoms are progressive dyspnea, variable cough, substernal chest pain, blood streaked sputum, decreased chest expansion, emaciation, weakness, clubbed fingers, or curved nails. Late in the disease, the dyspnea becomes distressing, cyanosis may occur, and there may be severe paroxysms of coughing productive of tenacious sputum. The characteristic chest X-ray shows granular or ground glass markings with more or less obliteration of usual linear pulmonic markings, localized in mid-lung and bases. The grainy appearance may become quite generalized with evidence of emphysema usually in the apices. Nodular or nodulo-conglomerate shadows of silicosis are not observed, but whether this is due to a peculiarity of asbestos dust or to rare occurrence of extremely high dust exposures, it is impossible to say. Shaginess of the heart shadow is not infrequently observed and seems to be most common in workers exposed to a high proportion of fiber (e.g., twisting, broadcloth weaving). By fluoroscopy, diminished excursion of diaphragm is seen. Peaking deformities of diaphragm, however, occur less frequently than in silicosis.

Asbestosis bodies found in the lungs and sputum are characteristic. There is good evidence that these bodies originate as a cellular response to inhaled fibers.⁹ Asbestosis bodies consist of a core of asbestos fiber surrounded by iron-containing protein deposits. They are golden yellow in color, and do not stain with ordinary histologic stains but become brilliant blue when treated with potassium ferrocyanide. They are variable in form and size and characteristically are slender, elongated, segmented structures with bulbous ends which give them a dumbbell or drum-

FIGURE II—Photomicrographs of Asbestosis Bodies Found in Sputum. Enlarged 530 Times (Except E, Which Is Enlarged 310 Times). A Scale, Ruled in Units of 50 Microns, Has Been Drawn Beside Each Asbestosis Body.

stick shape (Figure II). Occasionally a forked or Y-shaped body is observed. They range from 10 to 180 μ in length, averaging about 35 μ .

It has been suggested that damage to the lungs occurs while the body is being formed, but once the body is formed the fiber in the core is rendered inert by its coating of iron.¹⁰ The finding in the sputum of clumped asbestosis bodies in radial pattern or rosette

(Figure II E), which is common in lung sections, has been suggested by Stewart, Tattersall, and Haddow¹¹ as a clear indication of disintegration of lung tissue whether by a process of simple suppurative broncho-pneumonia, or as a result of secondary tuberculous infection. In either case, they feel that it strongly indicates a definite underlying asbestosis.

On single sputum specimen analysis

FIGURE III—Percentage of Males, Classified by Age, Who Had Certain Lung-Field Markings; 229 Men Had No Previous Industrial Dust Exposure, 80 Had Been Exposed to Kaolin Dust, and 357 Had Been Exposed to Asbestos Dust.

of each case, the incidence of asbestosis bodies increased with increasing dust exposure. They were found in sputum of 46.9 per cent persons whose condition was diagnosed as asbestosis, whereas 24.3 per cent of essentially normal asbestos-exposed persons had bodies in the sputum. They were not observed in any of the persons surveyed with less than 3 months' exposure. Since they may be found in the sputum before significant fibrotic changes have occurred, their presence is interpreted as merely showing evidence of exposure.

X-ray interpretations—During the development of a typical pneumoconiosis, the lung field appearances of chest roentgenograms pass through a series of rather well defined phases. Beginning with the normal adult film with its linear pulmonic markings, the first next appreciable change is an exaggeration of these markings. Then a ground glass or granular appearance is noted which gradually obliterates the linear markings, followed by nodular and nodulo-conglomerate markings. The lung field appearances in asbestosis do not appear to proceed beyond the ground glass or granular phase. Classification of all films was made according to phases. The apparent small amount of involvement of lungs makes it difficult to evaluate the severity of the case from an X-ray film only. The difficulties of interpretation of the chest films emphasize the importance of careful technic. As a form of pneumoconiosis, asbestosis strikingly indicates the necessity for clinical study of a case before diagnosis can be made. The film of a patient severely ill with asbestosis may have markings which would appear insignificant alongside a typical silicotic film of a man who is actively at work.

In the interpretation of asbestotic films the physician must be aware of exaggerated markings attributable to advancing age. This is illustrated in Figure III. One group comprising 229

men had never been employed in a dusty trade; the other included 80 men engaged in mining and refining of kaolin by wet methods. The percentage of men who have second degree exaggeration of linear lung markings increases with advancing age. It is significant that in this entire group of 309 men there were no cases of ground glass lung field markings, even though this change is observed in the asbestos workers. It appears that the reason why the incidence of the ground glass type of pulmonic marking is correlated with age is that older people have been exposed to dust for the longest time.

Occurrence of asbestotic lung changes—In Figure IV the heights of vertical bars represent the percentages of asbestos workers in different exposure groups who had ground glass lung field markings of either first or second degree. Seventy-six controls have been excluded from this tabulation and a number of workers whose dust exposure was not known have also been omitted.

Considering the four dust exposure groups, one at a time, there is a consistent and regular increase in the percentage of persons with these ground glass markings with increasing length of employment. Age, of course, also increases with length of employment, but these fibrotic changes cannot be ascribed to advancing age because the previous figure (III) showed that fibrotic changes of this degree are not to be expected in workmen of comparable age who are not exposed to siliceous dusts. Note the absence of cases with ground glass markings in the group exposed to less than 5 m.p.p.c.f.

Obviously, there are great differences between individuals in the time that elapses from their first exposure to asbestos dust and the time fibrotic evidence is observed in the X-ray film. In some persons this was much less than 5 years and in others it appears to be more than 10. Some of the difference

FIGURE IV—Percentage of Asbestos Textile Workers, Classified by Average Dust Concentration (Measured in Million Particles per cu. ft.) and Duration of Exposure, Found to Have Ground-Glass Lung-Field Markings.

is probably due to total amount of asbestos dust inhaled. Difference in amount of physical exertion may play an important rôle—a person in a sedentary job having a smaller need for oxygen inhales less air and consequently fewer particles of asbestos.

It was noted that the relation between dust exposure and the incidence of ground glass lung field markings was not a simple one. Even when length of employment was disregarded, it was found that incidence of these markings

was proportionately lower at 10 to 19.9 m.p.p.c.f. than it was at the next higher or next lower concentrations. Although it is probable that these differences represented sampling errors due to small numbers of exposed persons, it may be that asbestos fiber excites a different and possibly more severe reaction than asbestos particles.

On account of large labor turnover, as well as the short time that the plants had been in operation, no exact estimate of incidence of asbestosis can

TABLE IV

*Occurrence of Asbestosis in Relation to Dust Concentration and Length of Employment
Percentage With Asbestosis*

Dust Exposure, Million Particles per Cubic Foot		Years in Asbestos Industry		
		0 to 4.9	5 to 9.9	Over 10
0 to 4.9	Affected	2	1	0
	Exposed	84	19	5
	Percentage	2%	5%	0%
5 to 9.9	Affected	0	6	13
	Exposed	70	37	19
	Percentage	0%	16%	68%
Over 10	Affected	8	22	21
	Exposed	134	43	36
	Percentage	6%	51%	58%

be made. Table IV shows, however, that the percentage of persons with asbestosis increases greatly with increasing length of employment. Lanza, McConnell, and Fehnel¹² reported a similar trend. The incidence also increases with increasing dust concentration. For the reason that there are but few cases with more than 15 years' exposure, the percentages in Table IV are necessarily minimal estimates of prevalence of asbestosis even though several of the former employees are included.

SAFE LIMITS OF EXPOSURE TO ASBESTOS DUST

For practical purposes it is useful to have a definition of safe working conditions. Ideally, a threshold concentration of dust should be the highest dust concentration that would not produce pneumoconiosis in originally healthy workmen during their entire working life. Below 2.5 m.p.p.c.f. the interpretation of Table IV offered no difficulties, since none of 39 persons exposed to that concentration had asbestosis, although only 6 had been employed more than 5 years. Three doubtful cases of asbestosis fell in range 2.5 to 4.9 m.p.p.c.f.

Because clean-cut cases of asbestosis

TABLE V

Percentages of Workers Exposed to Certain Concentrations of Asbestos Dust in Asbestos Textile Factories Where Dust Control Measures Are Used to a Limited Extent and in Factories Where Effective Dust Control Is Practised

Dust Concentration Million Particles per Cubic Foot	Limited Use of Dust- Control Measures *	Extensive Use of Dust- Control Measures †
Over 10	48	7
5 to 9.9	28	17
2.5 to 4.9	15	32
Under 2.5	9	44

† Data from reference 13.

were found in dust concentrations exceeding 5 m.p.p.c.f., and because they were not found at lower concentrations, 5 m.p.p.c.f. may be regarded tentatively as the threshold value for asbestos-dust exposure.

A supplemental engineering study¹³ was made in an asbestos textile factory in which dust control equipment had recently been installed. This showed that means are already available for reducing the dust exposure of a majority of asbestos textile workers to less than 5 m.p.p.c.f. The basis of this control was exhaust ventilation near source of dust.

CONCLUSIONS

As in other forms of pneumoconiosis, occupational history, and clinical and X-ray (or pathologic) findings must be in harmony before a sound diagnosis can be made. The occupational history should be a reflection of manufacturing processes since the job designation refers to a stage in manufacture. The occupations which were found particularly liable to induce severe forms of asbestosis were willow, pick, card, spin, twist, and cloth weave. Confirmation of the hazardous nature of some of these occupations is the frequency with which the occupational designation of carder, weaver, or spinner is encountered in autopsy reports of cases.¹⁴⁻¹⁸ The following are the outstanding findings determined in this study:

1. In a study of 541 employees of North Carolina textile mills, pulmonary asbestosis was the principal physical defect found.
2. The most serious forms of the disease were observed in carders, spinners, weavers, twisters, willowers, and pickers.
3. Exposures ranged from 0.10 to 76 m.p.p.c.f.
4. Dust contaminants of air in asbestos textile plants are both particulate and fibrous.
5. It is imperative that findings of occupational history, clinical examination, and X-ray film all be considered in making diagnosis of a case.
6. Definite clinical and roentgenographic

evidence of asbestosis is observed in exposed persons after 5 to 10 years of work in exposures exceeding 5 m.p.p.c.f.

7. It appears that if asbestos dust concentrations in the air breathed are kept below 5 m.p.p.c.f. new cases of asbestosis will not appear.

8. Methods for controlling the dust below this tentative threshold are already available for most of the processes in the industry.

Factors Influencing Nonspecific Resistance to Infection^{*}

CHARLES F. CHURCH, M.D., F.A.P.H.A. †

Director, Rockefeller Nutrition Fund, Children's Hospital of Philadelphia, Philadelphia, Pa.

THE study of experimental infections in pure lines of mice has made possible the separate evaluation of host factors and parasite factors influencing the course and outcome of acute infectious disease.¹ When the parasite factors, including strain, virulence, dosage, and portal of entry, are maintained constant, the survival of the host following inoculation is conditioned by heredity, nutrition, and by environmental factors directly affecting the host.

In a previous report the resistance of young mice to mouse typhoid was shown to be greatly influenced by the diet of the mothers during pregnancy and lactation.² The environmental factors were maintained uniform by isolation of the inoculated mice in individual cages in an air-conditioned room. The purpose of this paper is to review the effects of heredity and of nutrition upon resistance to infection and to present a method for the evaluation of natural resistance independent of the development of specific immunity.

The results here presented are de-

rived from the study of 2,868 mice inoculated by stomach tube, at the age of 8-9 weeks, with a standard dose of *Salmonella enteritidis*. The technic employed has been described in a previous publication.²

The virulence of the test organism for this particular host has remained unchanged through these experiments. When the genetic background, the dietary background, and the external environment of the host were kept constant, the survival curves for groups of 20 mice were reproducible within the limits of statistical variation (Figure I). The first deaths occurred about the 6th day after inoculation and the point of 50 per cent mortality was reached on the 8th to 9th day. The mean survival at the end of 28 days was from 0 to 15 per cent. The uniformity of these results with groups of mice of the same genetic and dietary background indicates the constancy of host and parasite factors in these experiments. There is no evidence of seasonal variation in the periods covered (October to May and September to March).

The course of the experimental infection in the organs and tissues has been followed by bacteriological studies^{*} of mice killed on successive days following intrastomachal inocu-

the organism in the spleen for long periods after inoculation.

A. HEREDITY AND HOST RESISTANCE

The rôle of heredity in resistance to infection has been demonstrated by Webster.^{3,4} By selective breeding, lines of mice were developed which respond characteristically to a given infective agent. Three of these pure lines, obtained originally from the Rockefeller Institute for Medical Research, have been studied in our laboratory. They are designated as follows:

Line A — Rockefeller Institute Resistant (BRVS)

Line B — Rockefeller Institute Susceptible (BSVR)

Line D — Swiss Mice (Unselected)

Lines A and D have reached the 8th generation in our laboratory. Line B was discontinued after the 3rd generation in order to permit more detailed study of the other two.

When tested by inoculation with *S. enteritidis* these three lines of mice gave responses similar to those obtained by Webster. In a series of experiments (Figure II) Line A gave 89 per cent survival at 28 days after inoculation, and 44 per cent came through the infection with no evidence of illness. The contrast offered by Line B is striking, for of the latter 50 per cent were dead by the 8th day and less than 2 per cent (one animal) survived to 28 days. These two lines were developed by selective breeding from the same

FIGURE III—Differentiation of natural resistance from acquired specific immunity. The survival data shown in Figure II is plotted on arithmetic-probability coordinates

original stock and therefore demonstrate the marked degree to which heredity may influence host resistance when all other factors are kept constant.

Line D is a genetically unselected line and shows, as may be expected, a survival rate intermediate between the Resistant and the Susceptible lines: namely, 33 per cent.

The sigmoid shape of these curves suggests that they may be curves of normal frequency distribution of deaths with respect to time.⁵ This can be tested by plotting the results on arithmetic probability paper (per cent survival against time after inoculation). A straight line relationship will then indicate a normal frequency distribution. When the survival curves for the three lines of mice are plotted thus, there results in each case a straight line bent or deflected near the middle (Figure III). The point of deflection is from 9 to 12 days after inoculation and corresponds in time to the rise of the antibody titer in the blood serum of the infected animals.

The first part of the curve is obviously that determined by the natural resistance of the previously unexposed population, whereas the deflection of the lower limb indicates a change (increase) in the resistance of those that have survived the first onslaught of the infection. This increase in resistance, 9 to 12 days after inoculation, may be due to the rise of specific immunity.*

Since the upper limb of the curve is that determined by the nonspecific resistance of the group we have only to follow this line to its intersection with the abscissa for 50 per cent survival to obtain the mean survival time

uninfluenced by specific immunity. When the upper limb does not extend to the 50 per cent abscissa, as with the Line A curve, it may be extrapolated to the point of intersection.

The mean survival time obtained in this way is a measure of nonspecific resistance which can be applied to any homogeneous population tested with a suitable pathogen under controlled conditions.

B. DIET AND HOST RESISTANCE

1. *The contemporaneous diet*—Host resistance is not readily influenced by the diet during or immediately preceding the period of infection. Changing the diet within rather wide limits from the normal, 2 weeks before inoculation, had little effect upon survival. This was indicated in Webster's work⁷ and is borne out by the recent results of Topley⁸ and Watson.⁹

Certain changes in the contemporaneous diet, however, have a marked effect upon nonspecific resistance. The level of mineral salts in the diet is a factor of considerable importance.¹⁰ When the level of inorganic elements was reduced to one-fourth the normal, 2 weeks before inoculation, the fatality rate in Line A mice was increased from 9 to 34 per cent.² Drastic reduction in dietary calcium likewise resulted in increased mortality. When the calcium content of the diet was reduced from 0.55 per cent to 0.10 per cent the fatality rate increased from 12 to 59 per 100 animals (Figure IV). Uninoculated control groups maintained upon each of these low mineral diets suffered no fatality over a 10 week period.

It is possible, therefore, to influence host resistance by making the contemporaneous diet insufficient or unbalanced with respect to mineral salts. Our attempts to produce similar depression of resistance in Line A mice by deprivation of vitamin A, of vitamin

* The agglutinin titer in the sera of survivors after 28 days was 1:80 or greater, while the sera of mice killed 8 days after inoculation gave no agglutination in 1:20 dilution.

FIGURE IV—The influence of a marked alteration in the calcium content of the contemporaneous diet upon resistance to infection

FIGURE V—The effect of the diet during pregnancy and lactation upon the resistance of the offspring

D, and of fat have failed.¹¹ This, together with the evidence of the importance of the maternal diet, suggests that modification of resistance is not readily effected through the contemporaneous diet.

2. *The maternal diet*—The diet of the mother during pregnancy is a factor of major importance in determining the resistance of the offspring to mouse typhoid infection.¹² In our experiments comparisons were made between a simple diet of three ingredients (Diet 221) and a mixture of ten ingredients (Diet 200). These two diets were almost equally satisfactory for the breeding and rearing of Line D mice. When the progenies from these two maternal diets were placed upon the same diet and tested by inoculation with *S. enteritidis* the survival of those born of mothers on the diet of ten ingredients was significantly greater than the survival of those born of mothers on the diet of three ingredients. Of those born on Diet 200, 47.1 per cent survived the infection, while of those born on Diet 221 only 11.8 per cent survived. The statistical significance is indicated by the odds of 3,671 to 1.

In subsequent experiments the progenies from these two maternal diets were changed to the same purified diet during the contemporaneous period in order to rule out any effect of gastrointestinal contents upon the initial growth of the organism. The results were similar (Figure V). Survival in the progenies born on Diet 200 was 43.4 per cent, while in those born on Diet 221 it was 7.8 per cent. Because of the large number of animals used the statistical significance is very high.

Both of these diets were adequate for normal growth and reproduction and, by the usual criteria of growth rate, size of litter, fertility, and weight of young at 10 and 25 days, were almost equally satisfactory. Chemical

analysis¹³ revealed a number of differences in composition but gave little clue to the essential factors.² But the progenies from mothers changed at mating to the diet of three ingredients (Diet 221) showed low resistance, whereas those from mothers placed at mating on the diet of 10 ingredients (Diet 200) showed high resistance to the test infection. The improvement in resistance was greater when the change to diet 200 was made 8 weeks or more before mating. Successive generations on the resistance-inducing diet showed progressive increase in survival percentage. The greatest increase in resistance (survival of 79 per cent as compared with 7 per cent) was obtained after three generations on the resistance-inducing diet (Figure VI).

These differences in the host resistance of young mice from the two maternal diets appear to be the result of differences in the nutrition of the mothers. The possibility of variations in the genetic constitution of Line D mice as a result of heterozygous matings cannot as yet be ruled out absolutely, since strict sibling mating has been practised for only 8 generations. However, in view of the consistency of the survival responses of progenies from the two maternal diets this possibility appears remote.

Watson⁹ has recently reported resistance tests on mice maintained on 8 different diets. The young were subjected to the test diet either from the prenatal period onward or for only 3 weeks before being tested. At 12 weeks of age they were inoculated with mouse typhoid (100 million organisms by mouth) and were placed in individual cages. The hereditary factor was not controlled, the stock mice having been obtained from several different breeders. In spite of the differences in technic the results appear to be essentially in agreement with those given here. Three weeks on the test diet

FIGURE VI—The influence of the maternal diet, continued for four generations, upon the resistance of the offspring

before inoculation had no apparent effect upon resistance, whereas exposure to the influence of certain diets from the prenatal period onward gave rise to significant changes in resistance.

SUMMARY

Nonspecific resistance to infection has been studied in 2,868 mice of three lines, inoculated with *Salmonella enteritidis*. When the external environment and the parasite factors including strain, virulence, dosage, and portal of entry, were kept uniform, the survival of mice at risk was dependent upon heredity and nutrition.

When the dietary background was kept uniform the three lines of mice gave mortality responses in agreement with those obtained by Webster. The time-survival data of each line gave a normal frequency distribution truncated at 9 to 12 days after inoculation. The point of truncation appears to

coincide with the antibody response of those that survive the first onslaught of infection.

By graphic analysis the mean survival time of the original population, independent of the effect of specific immunity, can be derived. It is suggested that the mean survival time obtained in this way is a measure of nonspecific resistance which can be applied to any homogeneous population tested with a suitable pathogen under controlled conditions.

The diet of the mother before and during gestation was a factor of major importance in influencing the resistance of the offspring to the risk of infection. The protection thus afforded lasted at least until maturity was reached, and progressive improvement took place for at least three generations on the same diet. The influence of diet upon resistance may thus be on a par with the influence of heredity.

Explanation of Charts: Each curve represents a group of mice (usually 20 or multiples of 20) of the same genetic and dietary background, inoculated by stomach tube with a standard dose of *Salmonella enteritidis* and kept under observation for 28 days. Survival *per cent* is plotted against time in days.

The clinical condition of the surviving group is shown by the vertical columns at the right: W = Well through entire period; R = Ruffed fur only; S = Sick; C = Convalescent.

The statistical analysis in Figures IV and V is indicated as follows: Diff. = Difference between survival percentages at 28 days; S.E.D. = Standard Error of the Difference =

$$100 \sqrt{PQ \left(\frac{1}{n} + \frac{1}{n'} \right)};$$

Odds against the observed difference being the result of chance.

NOTE: I acknowledge my gratitude to Dr. L. T. Webster, Dr. J. C. Gittings, Dr. Joseph Stokes, Jr., and the Rockefeller Foundation for the opportunity of conducting this study; My appreciation to Miss Claire Foster and Miss Dorothy W. Asher for assistance in carrying it on.

A Hopeful View

PULMONARY tuberculosis is a chronic systemic disease with a decided tendency to heal. The chronicity, inherent tendency to heal, and curability are due to a beneficent auto-immunization. Were this not true the human race would long since have vanished. This chronicity, when the disease is untreated, inadequately treated, or

unrecognized, is responsible for its continuous contagion and universal distribution, for a reducible economic waste and disability, and for a certain irreducible mortality rate. . . . Production of Antipneumococcic Rabbit Serum*

B. SCOTT FRITZ, V.M.D.

The Gilliland Laboratories, Marietta, Pa.

ANTIPNEUMOCOCCIC Rabbit Serum, Therapeutic, introduces the clinician to an entirely new product in the field of serum therapy. The results obtained from the use of immune rabbit serum in the treatment of pneumococcic pneumonias in the Hospital of the Rockefeller Institute for Medical Research, New York,¹ and Long Island College of Medicine,² indicate that the serum is an effective adjunct in the treatment of pneumococcic pneumonias. Recognition is given those from the Hospital of the Rockefeller Institute for the pioneer work that has been done with antipneumococcic rabbit serum. The report on the production, processing, and standardization of antipneumococcic rabbit serum,³ is informative and of great value to those interested in the many phases of this work.

This report is submitted with the hope that it may prove of some interest to those producing or who may anticipate the production of type specific antipneumococcic rabbit serum. It deals with the production of serum as carried out in a commercial laboratory. The methods were developed following the counsel and literature of those mentioned. The report further deals with

the rabbit mortality incident to the production of type specific sera from a colony of approximately 1,000 rabbits.

ESTABLISHING THE COLONY

It is no small undertaking to establish a sizeable colony of rabbits and maintain it in a state of health conducive to the economic production of immune sera.

After thorough consideration of the problems involved, reliable sources for rabbits were contacted with the hope of arranging a satisfactory plan for purchase. Those interviewed were willing to supply rabbits subject to approval. Conditions of sale specified that the rabbits be in an acceptable condition of health, weigh 4 lbs. or more, and be preferably of the New Zealand Red or Chinchilla breed. It was further specified that young rabbits were preferred and all stock must have a good ear with a visible marginal ear vein. They were purchased at a given price per lb. which was considered fair and acceptable for the purchaser and seller. The rabbits delivered to the laboratory were carefully examined, the history of their origin noted, in so far as disease was concerned, weighed, and segregated in a unit specially planned for the purpose. During the early period of partial isolation, and as soon as was practicable, all rabbits were injected subcutaneously with 5 c.c. of polyvalent

* Read before the Laboratory Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 28, 1938.

whole culture antihemorrhagic septicemia bacterin. After isolation of 10 to 14 days, the rabbits were moved into the unit designed for the producing group. During isolation they were examined daily for symptoms of infectious or contagious disease. Fortunately the source of supply was good and most of the rabbits purchased had been raised on local farms or in comparatively small colonies. Rabbits were occasionally rejected and if one or more were rejected in a particular shipment, all exposed to those individuals were likewise rejected, particularly if an infectious disease was suspected.

In view of the fact that rabbits under immunization are handled as frequently as 4 and 5 days a week, they should be housed in suitably designed buildings, and in cages conducive to a saving of time and labor. The two houses being used are 125' long by 20' wide with 8', 10" ceilings. They are well lighted by windows which provide adequate ventilation without draughts. Cupolas provide additional ventilation. Buildings are insulated to eliminate excessively high temperatures during the summer and each building is equipped with an automatically controlled oil burner fuel system which has very satisfactorily maintained an even temperature during the fall, winter, and spring. The mortality among our rabbits due to excessive heat, draughts, and similar conditions frequently responsible for many deaths in a colony not satisfactorily provided for, has been negligible. A temperature of approximately 50° F. during those months when the atmospheric temperature was considerably lower, seems ideal. The colony during the winter months has shown some evidence of snuffles. This condition was easily controlled by the addition of cod liver oil to the diet. The colony has experienced no outbreak of any disease of an infectious character.

The buildings are so designed as to

provide for a row of cages on each side with a double row through the center. The cages in the center are 6 high and house 48 rabbits per section. The same number of sections are provided on each side of the buildings with the exception of beneath the windows where the cages are but 4 high. Rabbits are individually caged, the size of the cage being optional, though one 26" wide, 20 $\frac{1}{4}$ " deep and 14" high is adequate. Water is supplied each rabbit by means of an inverted glass bottle fitted with a rubber stopper through which is inserted a piece of brass tubing. The rabbit laps the water from the projecting tube. The containers are very serviceable and it has been of interest to note that most rabbits will consume 8 to 10 oz. of water a day throughout the year even when moist, green food is supplied as part of the diet.

The alleyways between cages are 4', 10" wide allowing ample space for the cleaners to move their carts. The individual cages have metal floors, are cleaned every other day, thoroughly washed and sprayed with a 4 per cent solution of cresol, then rebedded with clean, dry shavings. Sanitation has been maintained at all times and this factor is essential in the successful maintenance of a healthy rabbit colony.

Identification of Rabbits

Each rabbit is identified with an ear tattoo number before being assigned to the production of a specific serum. A letter or number prefix identifies the type of serum the rabbit is to produce. The rabbits are weighed and on a card attached to the cage is recorded the weight, tattoo number, and date of entry into the colony. Individual charts are kept for each rabbit, giving similar information together with a record of immunization, bleedings, and such other data as may be pertinent to the history of the animal during its life in the colony.

FEEDING

Producing rabbits, in addition to being well housed in clean, sanitary cages, should be fed a well balanced palatable diet. The rabbits purchased, coming from many sources, are undoubtedly fed a variety of diets. Animals do not do well when decided changes are made in their diets and for this reason we consulted those supplying rabbits to learn, if possible, the foods most generally fed. This resulted in such a great variation that it was necessary to arrange for a feeding schedule that was attractive to the majority of purchased rabbits. A commercially prepared food has proved entirely satisfactory. The rabbits relish this and during the production of serum have steadily gained weight, which seems to be a reliable indication of a good food. In addition to the commercially prepared food, alfalfa, carrots, cabbage, beets, etc., of a good quality are supplied as a supplement from time to time.

BACTERIAL SUSPENSIONS FOR IMMUNIZATION CULTURES

It has been proved that virulent cultures are essential for the preparation of bacterial suspensions that will be most effective in the production of a serum of high titer in animals.⁴ Type specific pneumococcus cultures are used in the smooth phase, where it is possible, and mouse virulent strains are used exclusively. The cultures being used at the laboratory are infective for mice, though some possess little or no virulence for rabbits. It is our opinion that cultures virulent for rabbits and mice are more desirable than those virulent for mice only. It has been observed that strains of pneumococcus possessing little or no virulence for mice are rarely virulent for rabbits. The cultures used for immunization should be passed each week or more frequently through either mice or rabbits, or both mice and rabbits for the maintenance of virulence.

Beef heart phosphate broth to which has been added 1 per cent defibrinated blood is used as a stock broth. Cultures for animal inoculation (virulence test) are seeded from this to the same broth to which dextrose has been added, grown for varying lengths of time, approximately 4 to 8 hrs., then diluted for animal passage. The range of dilution varies in respect to the virulence of the type specific pneumococcus. All cultures are identified for specificity as well as cultural characteristics before being inoculated into broth for antigen production. The virulent strains have retained their smooth phase and virulence for many months for mice and rabbits. All strains are not rabbit virulent.

Broth

Each lot of beef heart phosphate broth is tested for its suitability and natural muscle sugar content. It is important to establish the broth as a suitable medium and this is done by tubing 20 c.c. samples from each lot. A varying amount of dextrose (.02 per cent to .08 per cent by volume) is added to each of the tubes, and each tube is inoculated with the selected strain of the pneumococcus, grown 16 hrs. at 37.5° C. and pH determinations made from the broth at the end of the growth. The amount of dextrose finally added to the lot of broth is governed by the tube which shows the optimal pH. A pH between 6.6 and 6.8 is considered optimal (within the desirable range) and the dextrose broth tube giving that titration is selected as the tube containing the ideal amount of dextrose to be added to that particular lot of broth. This may be considered an unnecessary precaution but the procedure is simple and has resulted in the production of entirely satisfactory bacterial suspensions of Gram-positive staining organisms. Certain type specific pneumococci grow very rapidly and these should not be grown at 37.5° C. for the same number

of hours for the preparation of an ideal suspension for immunization.

The antigen for immunization is prepared from the first transplant recovered from the mouse, or rabbit, and is seeded in bulk containers of broth containing not more than 3 liters. The inoculation of a large volume of broth is not as satisfactory as small volumes in the production of good bacterial suspensions. After the pneumococcus is grown for the time assigned by previous determinations for each lot, the bulk container is removed from the incubator and preserved with 1 per cent formalin. The containers are kept at room temperature until the evening of the day they were preserved; then placed in the cold box until the following morning, when the organisms are collected and resuspended in a 0.1 per cent formalized salt solution. Early in the work no attempt was made to standardize the suspension. It was noted, however, by resuspending the organisms in a definite volume of formalized salt solution representing one-tenth of the original volume of broth that the resulting suspensions were of varying turbidity, though quite uniform in staining characteristics. For this reason it was advisable to standardize the suspensions by some simple and practical method. The suspensions are now standardized to the approximate turbidity of 10,000 million typhoid bacilli per c.c. Standardization of the suspension seems advisable so that a uniform suspension is used throughout the course of immunization, particularly if the doses for immunization eventually become constant. It is appreciated that the accuracy of standardization depends upon the Gram staining structure of the bacterial suspension. Therefore, if the bacterial suspensions have autolyzed standardization is of little or no value. It has further been shown³ that most pneumococcus suspensions possess little toxicity for rabbits and that they tol-

erate wide variations in the number of suspended bacteria without bad effect.

Channel of Immunization

The intravenous method of immunization is used exclusively and the marginal ear vein the portal of entry. Cole and Moore demonstrated conclusively that intravenous immunization was essential for the production of immune sera of high titer.⁴

IMMUNIZATION AND BLEEDING SCHEDULES

It is natural that consideration be given to the production of an immune serum of high titer and to the plan of immunization that is conducive to the maintenance of the animal in a satisfactory state of health and over the longest period of time. The schedule of immunization carried out by Goodner, Horsfall, and Dubos,³ known as The Four Week Complete System, has been followed in its entirety with the exception that the holding dose has been 0.2, 0.5, 1, and 1 c.c. rather than 0.2, 0.5, 1, and 2 c.c. It was found necessary to reduce the 2 c.c. dose as will be shown later in the charts on mortality, hoping to reduce the mortality following this dose. The bleeding schedule has been followed in accordance with the plan.

BLEEDING

Rabbits are bled from the heart by cardiac puncture. The precardial area is clipped and wiped with cotton saturated with alcohol. The rabbits are fastened to a bleeding board by means of straps to their four feet with the ventral surface exposed to the operator. A sterile cloth is placed over the rabbit and bleeding board with a window cut out over the area of the chest, thereby exposing the region to the operator. Cardiac puncture is made with an 18 gauge needle attached to a sterile 50 c.c. syringe, the syringe having previously

been rinsed with sterile double normal strength salt solution. Cardiac puncture is made from a point of insertion just left of the median line at the margin of the xyphoid cartilage. This line of entry to the heart is used in preference to that of entering between the 4th or 5th rib. It enables the operator to withdraw blood from the heart without passing through the lung. Cardiac puncture by this channel into the left ventricle is more direct and the mortality following bleeding has been noticeably reduced. Many operators may not prefer this method of bleeding. Several methods of withdrawing blood have been used, the first was by creating 8 to 10" of vacuum in a bottle to which was attached a syphon with a needle adapter. It was discarded, however, in preference of the syringe method, where the operator was able to determine the exact amount of blood being drawn from the heart. Fifty to 60 c.c. of blood are taken at each bleeding. The serum recovered has been approximately 60 per cent of the blood drawn. The blood is collected in tubes 500 mm. in length and 65 mm. in diameter. They conveniently hold approximately 800 c.c. of blood. The blood is permitted to clot at incubator temperature after which the serum is drawn off, centrifuged, if necessary, pre-

served with methiolate to a concentration of 1 to 10,000 and filtered through a Berkefeld N. candle. The serum from the remaining clot in each tube is pressed out by dropping weights that have been attached by means of a pin through a rubber stopper prior to sterilization. The blood is delivered to the tube through glass tubing that has a removable cotton and gauze closure. This enables one to handle the serum aseptically and has proved practical and entirely satisfactory.

The 1,000 rabbits considered in this report have been immunized for the production of Type I, II, V, VII, VIII and XIV antipneumococcic sera. The data reported are taken from this group as a whole, and cover 1 year only. It may be noted, however, that at the end of the time, a small percentage of the group remain.

From the original colony of 1,000 rabbits, 6,114 bleedings were made from June 30, 1937 to July 1, 1938. Of the 1,000 rabbits 421 died following bleeding. These deaths are directly attributable to bleeding and occurred within 24 hours following. Two hundred and two died during the course of immunization, and their death may be directly attributed to the injection of the bacterial suspensions. One hundred and forty-two died from other causes not asso-

CHART I—Distribution of 406 rabbit deaths due to bleeding

CHART II—Distribution of 324 rabbit deaths due to immunization

ciated with either bleeding or immunization. Injury has not been a factor in mortality rate.

It may be noted from the figures on mortality, considering the total number of deaths of rabbits from all causes that a rabbit in the colony has a life expectancy of approximately 9 bleedings.

During the year, 765 of the rabbits, or 76.5 per cent, died from all causes and 235, or 23.5 per cent, are in the colony and continue as producing rabbits.

For 1 year, exclusive of the rabbits remaining in the colony, 1 death occurred for each 14.5 bleedings. The 23.5 per cent of rabbits remaining in the colony however, may materially increase the number of bleedings per rabbit death.

The cost factor has not been discussed in connection with the production of type specific antipneumococcic rabbit serum. Simple calculations, however, will reveal the cost to be equal to, if not greater per c.c. than, antipneumococcic horse serum.

It may be noted from Chart I that

the high mortality rate occurs during the first 10 bleedings. The percentages have been calculated on the basis of the number of rabbits dead following each bleeding compared to the total number of bleeding deaths. Of the 406 rabbit deaths due to bleeding, 8.1 per cent occurred with the first bleeding, 8.4 per cent with the second, 10.1 per cent with the third, and so on as represented. It is believed that the weaker rabbits not able to tolerate bleeding are self eliminating early in the program. The chart offers little other than the natural resistance of a colony to scheduled bleedings.

Chart II shows the distribution of 324 rabbit deaths due to immunization. The 324 deaths have been illustrated by columns showing the series of immunizations during which they occurred. The columns are subdivided to illustrate after which injection deaths occurred.

Each column and each column portion has been diagrammed from actual calculated percentages.

The second and third series of immunizations claim the greatest mortality, hence rabbits highly sensitive to the antigen are evidently weeded from the colony.

Beginning with the start of bleedings and the fourth series of immunization (see Immunization) it is interesting to note that the gradual rise in percentages of deaths are regularly reduced after each four series of immunizations by the scheduled rest period.

The relative per cent of deaths which follows the first and fourth injection of antigen in nearly every series is of interest. Before reducing the amount of the fourth injection in each series the rise in mortality after the fourth injection was more accentuated.

DISCUSSION

The management of a rabbit colony plays an essential part in the economical and successful production of immune sera.

Those responsible for production should arrange for their supply of rabbits from reliable sources. Purchases should be restricted to rabbits of desired weights, and of healthy stock. The rabbits should be individually caged and comfortably maintained under sanitary conditions, free from draughts. Feed should be of good quality, and sufficient to maintain the body weight of the rabbit in production. Fresh water supplied daily is a safe practice.

A satisfactory bacterial suspension is the prerequisite to an immune serum of satisfactory potency. This is first accomplished by maintaining the virulence of the type specific pneumococci,

growing them in a suitable medium and for an optimum period of time to prevent autolysis.

Accurate records are equally essential and without them the scheme of production and results obtained are of no value.

Rabbits respond to careful handling. Bleeding technic is best developed through practice and each laboratory will develop its individual method, which is best suited to it with the hope of reducing the mortality from bleeding.

Immunization schedules may vary depending upon the plan of those responsible for production. Intense schedules of immunization are apparently responsible for a high mortality and may not produce sera as high in unitage as schedules less intense with longer intervals of rest. Chart I, however, indicates that the bleeding mortality is regularly higher following rest periods.

If less than 50 c.c. of blood is taken from the rabbit of 4 to 5 lbs., with no rest periods, the mortality following bleeding and immunization will be materially reduced. Further data may support this.

ACKNOWLEDGMENTS

The writer wishes to extend his appreciation to those who assisted in keeping records which made this report possible. John Hohenadel's efforts to obtain data in connection with this report are especially appreciated.

Rural Field Experience for Public Health Nursing Students*

PEARL McIVER, R.N., F.A.P.H.A.

Senior Public Health Nursing Consultant, U. S. Public Health Service, Washington, D. C.

PROFESSIONAL education has gone through three stages in its development. The earliest was the apprentice stage where any one wishing to become a physician or a lawyer attached himself to a successful practitioner of his chosen career and, through observation and practice under his preceptor's direction, acquired the necessary training. Later the pendulum swung to the opposite side and practically all of the professional education curriculum was planned as intramural instruction.

The present-day trend in modern education, whether in the field of medicine, dentistry, law, cultural education, or public health, is toward a combination of theoretical instruction with practice under expert supervision as the most satisfactory plan for the preparation of any professional worker.

The objection to the apprentice system of education centered around the fact that the learner was required to do much that had little or no educational value in order to pay his instructor for the education he was supposed to receive. Frequently he was required to do certain types of work over and over long after he had mastered the

technics. Others found that their training had been very one sided and that there were many fields in which they had had no training or experience.

Field experience, as a regular part of a university curriculum in public health nursing, is fraught with the same dangers as the old apprentice system. Students may be assigned to agencies where they are required to assist the organization by performing routine tasks over and over, day after day, and little or no effort is made to teach them the proper application of public health nursing principles. The agency may not be wholly to blame for this. The field agency may be required to take students without any remuneration, and a good field practice program costs money. Naturally the agency tries to get its remuneration from student work. Or, the agency may not be equipped to give a satisfactory educational experience, and in that case it should not have been selected by the university for that purpose.

It follows that the success of the student's field experience depends upon a number of factors:

Is the field agency organized on a sound administrative basis?

Is the program carried by the agency well balanced and typical of most health programs?

Are the members of the professional staff equipped to serve as instructors?

* Read at a meeting of the Committee on Professional Education at the Sixty-seventh Annual Meeting of the American Public Health Association, Kansas City, Mo., October 27, 1938.

Has the university, or some other department, arranged to reimburse the field agency for the expense of teaching students?

Are the students detailed to the agency for a sufficient time to make it possible for them to participate in all of the various phases of the health program?

Have arrangements been made to provide individual transportation for the students?

These, and many other questions, were asked of all of the universities and colleges in the United States which offer approved courses of study in public health nursing. Replies were received

from all but 2 of those to which the questionnaires were sent. Three universities replied that they were not at present offering rural experience to their public health nursing students. Two of the colleges sent information about the state health department of their respective states rather than on the local health agencies, and thus the information was not comparable. Fairly complete returns were received from 10 colleges and universities, and the comparable information received from the

other 2 colleges was included in the final tabulations.

AGENCIES USED FOR RURAL FIELD EXPERIENCE

According to the information collected in this study, 40 different rural health agencies were utilized in giving rural field experience to 440 public health nursing students last year. Three of the agencies were used by two universities. Both the University of Michigan and Wayne University sent students to the Michigan Community Health Project (the project financed by the Kellogg Foundation) and to the Children's Fund of Michigan. Peabody College and the College of William and Mary both sent students to the rural teaching center in West Virginia. Therefore, in the preparation of the tables which follow, these agencies were counted but once, even though they were used by more than one university.

From Table I it will be seen that 26 of the agencies used for rural field experience were organized as county health departments, 7 were district health units, and 7 were county nursing services only.

Table II gives a very sketchy picture of the personnel employed by these agencies. All but 7 were under the direction of whole-time health officers; 28 employed full-time local nursing directors or supervisors; of the 12 which did not have local nursing supervisors, 5 were one-nurse services, 4 had but 2 nurses, and 3 had only 3 nurses; 31 employed one or more sanitation officers. The 7 county nursing services and 2 of the county health departments had no sanitation personnel.

A total of 273 staff nurses were employed by these 40 agencies. The size of the staff varied considerably. Five agencies had but 1 nurse, while 10 had staffs of 10 or more nurses.

A public health council or advisory health committee made up of com-

munity leaders and representatives of voluntary health agencies is considered by many health administrators to be a valuable and necessary adjunct to sound local health organization. Twenty-four of the 40 rural agencies had a local advisory group of some type. However, some of the advisory boards or councils were made up entirely of county or township officials, and others represented only professional groups such as medicine and dentistry.

It is generally agreed that a good teaching agency should be one which is a "going concern" and has a well developed program. More than half of the 40 rural agencies had been in operation 10 years or more. However, 8 of them had been organized during the last 3 years and may not have had time to become stable organizations.

QUALIFICATIONS OF STAFF

While no attempt was made to secure information on the qualifications of any of the health department staff except the nurses, it is recognized that the health officer and other personnel must be well qualified public health workers if the nursing student's experience is to be satisfactory.

Of the 28 nursing directors or supervisors who were employed by these rural health departments, all of them were high school graduates, and 19, or about 68 per cent of them, had academic degrees. Twenty-three, or about 82 per cent, had certificates in public health nursing or had completed an equivalent amount of work in an approved public health nursing course of study; 11, or about 41 per cent, had had special preparation in supervision of public health nursing (Table III). Several had had special training in obstetrics, venereal disease control, or tuberculosis work.

Of the 273 staff nurses who were employed by these agencies, only 4, or less than 2 per cent, had not completed

high school. One hundred and ten had academic degrees and 218, or about 80 per cent, had completed an accredited course of study in public health nursing. In addition, 10 of the staff nurses had had special courses in supervision, 20 had had additional work in tuberculosis control, 8 had had special courses in venereal disease work, 9 had had special pediatric work, 6 special prepa-

ration in orthopedics, and 2 special courses in obstetrics.

From a comparison of the qualifications of the nurses employed by these agencies with the data obtained from former studies of the qualifications of nurses in official agencies, it would appear that agencies having staffs with superior qualifications had been selected for rural public health teaching centers.

PROGRAMS OF AGENCIES GIVING RURAL PUBLIC HEALTH NURSING EXPERIENCE

All agencies reported that their programs included the control of acute communicable diseases, and home visiting in the control of tuberculosis and venereal diseases. Twenty-eight, about 74 per cent, included diagnostic clinics for tuberculosis in their programs, and 21, or about 55 per cent, conducted venereal disease treatment clinics.

All of the agencies included maternal hygiene in their programs, but none offered a complete maternity nursing service including nursing assistance at delivery. Only one reported no pre-natal visiting. All reported postpartum visiting, but in the majority of cases it would appear that these visits were made in connection with the infant health supervision visits and that no actual postpartum nursing care was given. Fourteen stated definitely that no bedside nursing care was given even as a demonstration. All of the remaining agencies stated that nursing care

was given in emergencies and for demonstration purposes.

All carried an infant health supervision program but in 11 this service was confined to nursing visits to the homes, no group conferences or medical clinics being held. All included a school health service. All but 6 of the 40 reported that the nurses carried on some type of group teaching either in the high schools or with adult groups.

In general, it may be said that with the exception of nursing care to the sick, the rural agencies appear to carry a more completely generalized public health program than do many of the city agencies which have been used for student field experience. However, a really complete program in any of these services may not be possible when the population which each of the rural staff nurses is expected to serve is taken into consideration. The smallest population served by any one nurse in the group of agencies was 5,000, and in some there was but 1 nurse to 30,000 people. Obviously, regular maternity and bedside

nursing services would not be possible under those conditions, and it is probable that some of the other services were spread rather thinly.

RELATIONSHIP OF FIELD AGENCY TO THE UNIVERSITY

Eight of the universities and colleges offering rural field experience to public health nursing students appoint the supervising nurse of the field agency to the teaching staff of the university. Three of the universities employ full-time field instructors who work closely with the field agencies, coördinating the student's field experience. The educational supervisor of the state health department who has an appointment to the teaching staff of the university serves in this capacity in one state.

While all of the universities and colleges require the students to pay tuition for field experience, only 13 of the 40 field agencies received any remuneration from the university for the field teaching which they provided. The amounts received by the 13 agencies which were remunerated varied astonishingly. Several received a flat grant of \$600 a year without regard to the number of students; 1 received a grant of \$1,300 annually, and another 25 per cent of the salary of the nursing supervisor, 16 per cent of a staff nurse's salary, and 20 per cent of the salary of an office clerk. Several of the universities reimburse the field agencies by giving them a percentage of the tuition paid to the university. On a student basis, the fees received by the rural field agencies ranged from \$7.50 to \$85 a month! The median fee for each student per month was \$30. This was also the mode or the sum which was most frequently paid by the university to the field agency for field experience.

RATIO OF STUDENTS TO STAFF

It was encouraging to note that no

agency had more students assigned to it, at any given time, than the number of staff nurses. Nine agencies reported that, at certain times during the year, there were as many students on duty as there were staff nurses; but from the total number of students assigned for the year, it was apparent that the student load was not continuous. There were periods when there were no students assigned. The other agencies reported a ratio of less than one student per staff nurse.

LENGTH OF PERIOD FOR RURAL FIELD EXPERIENCE

The period for which students were assigned to rural agencies for field experience varied from 1 to 14 weeks. The majority of the agencies stated that students were assigned to them for 4 weeks. The University of Oregon stated that 4 weeks had been the usual time assigned to rural experience but that beginning this fall (1938), students would devote to it an entire quarter (11 weeks). The University of California has usually required an entire quarter's work with a rural agency. Western Reserve University has arranged for 1 week of observation for all students and a 6 weeks' experience with a rural agency for students who elect rural work.

TRANSPORTATION OF STUDENTS WHILE IN RURAL FIELD

"Field experience" implies actual participation in the field work. Field observation naturally precedes actual participation in the work; but unless the student is given an opportunity to carry certain responsibilities and serve as a member of the staff the experience is of less value. In rural areas it is essential that some provision be made for transportation if the student is to have an opportunity to function as a staff worker.

Of the 40 agencies on which informa-

tion was obtained, very few reported an adequate plan for providing transportation. Vanderbilt University owns several cars which are assigned to Rutherford County (which serves as the rural field for that school); these are used by the students, and by the staff of the health department during the student's observation period. Two of the universities pay for gasoline and oil for students who have their own cars. Two of the agencies in California furnish cars for student use. Students are assigned to these agencies for 14 weeks' experience, so are more capable of doing individual work than are those who stay but 1 month. A number of the agencies reported that the students owned and operated their own cars. Students who receive a stipend from Social Security funds are sometimes expected to use a part of their stipends for this purpose. The majority of the agencies reported no regular plan for transporting students, and stated that the student merely traveled with one of the regular staff.

SUMMARY AND CONCLUSIONS

The following principles are considered by many public health nursing educators to be desirable in establishing a rural field experience center:

1. The agency selected should be an organized county or district health department which has developed a well rounded health program. All personnel employed by the agency should meet the minimum qualifications for their various types of work.

2. There should be at least one whole-time nursing supervisor responsible for the student program who is eligible for faculty appointment in the college or university with which the agency is affiliated. If there are more than 6 or 7 staff nurses a second supervisor, to function in an educational capacity, should be provided.

3. A satisfactory relationship between the agency and the university should be worked out which would:

- a. Provide reasonable compensation to the health agency for the field teaching
- b. Give the health officer and supervising

nurse faculty appointments in the university as field instructors

- c. Establish a regular plan for conferences on student experience between the faculty of the university and the supervisory staff of the field agency

4. The number of nursing students assigned to the field agency at any one time should never exceed the number of staff nurses employed by the agency. It is preferable not to have a continuous student load. Periods when no students are assigned to the agency are highly desirable.

5. The student should be assigned to the agency for at least 6 weeks of continuous experience, and preferably longer.

6. The student's experience should include both observation and actual participation in all phases of the health program. This requires some specific provision for student transportation.

In checking over the present facilities for rural experience for public health nursing students, it appears that:

1. The majority of the agencies now used for this purpose meet the minimum requirements in so far as organization is concerned. All but 7 of the 40 agencies are organized health departments under the direction of whole-time health officers. However, 9 of the agencies had no sanitation personnel.

2. The programs carried by the various agencies are fairly general and cover the usual health department activities. However, there is need for an increase in the number of staff nurses employed by all of the agencies if each nurse is to have a reasonable case load. No nurse can carry on a satisfactory generalized public health nursing program if she is serving from 10,000 to 30,000 people. There is need for more emphasis on the giving of nursing care, particularly as a demonstration, if the service rendered is to be really effective.

3. Only 28 of the 40 agencies provided full-time local nursing supervisors. Naturally an agency cannot provide a supervisor for a staff of one or two nurses. There are certain advantages in having experience in the smaller and less complex agencies. If the local staff nurse is well qualified as a teacher, as was the case in one or two of the one-nurse counties, the situation may be satisfactory. However, the population per nurse was so great in most of the one or two nurse agencies that it is difficult to see when the staff nurse had time for supervising a student.

4. The qualifications of the nursing per-

sonnel were exceptionally high. Practically all of the staff met the minimum qualifications recommended by the Professional Education Committee of the American Public Health Association, and many of them exceeded those qualifications. The majority of the supervisors and a large percentage of the staff nurses would qualify for faculty appointment to a university although only 8 universities have adopted that practice.

5. The number of students assigned to the agency at one time appears to be satisfactory. No agency admitted more students at one time than it had staff nurses. In the majority of the agencies the ratio was less than one student to one staff nurse.

6. Only one university assigned students to the field agency for less than 1 month. One month was the most frequent assignment made last year, but 2 universities indicated that students would be assigned to the rural agencies for longer periods beginning this year.

7. Very few universities or agencies have worked out a satisfactory plan for the

transportation of students. If the student always accompanies a staff nurse, there is little opportunity for individual student practice. A satisfactory plan for student transportation is a universal need.

8. Twenty-seven of the 40 agencies which provided rural experience for public health nursing students last year did so without any remuneration from the university. A good teaching program is expensive. The university cannot expect teaching of good quality from volunteer instructors. In some of the states, the state health department gives additional aid to the agency used for field training. Since a well organized field teaching center may be used by the state health department for a variety of useful purposes, such a plan may be a partial solution of the problem. At any rate, it must be remembered that the health department's first obligation is to the community. Unless good service to the community is the first objective of the field agency, it is not likely to have a program that is worth while for student experience.

Place of the Methylene Blue and Resazurin Reduction Tests in a Milk Control Program*

C. K. JOHNS, PH.D.

Senior Assistant Scientist (Bacteriology), Science Service, Dominion Department of Agriculture, Ottawa, Ontario

THE control of raw milk supplies rests largely upon frequent routine bacteriological examination. Opinions may differ concerning the relative value of the three official tests (plate count, direct microscopic count, and methylene blue reduction test), yet when used with a proper appreciation of their limitations, each can assist in bringing about a considerable improvement in quality.

For the ordinary run of milk for pasteurization the plate count is practically disqualified by reason of greater cost and delay in obtaining results. There is also evidence that it is a less reliable indicator of utensil contamination than is the Breed count or reduction test.²⁵ The Breed smear without question furnishes the most complete information, both qualitative and quantitative. It is at its best with the very poor milks, declining in accuracy as the count decreases.^{19, 28} As milk supplies improve,

therefore, a stage is reached where doubtful reliance can be placed upon the Breed count without greatly increasing the number of fields examined. This stage has already been reached in some cities. The need for a technically trained worker and expensive equipment, as well as the fatigue involved, are also factors tending to limit the use of this method. The reduction tests, on the other hand, do not involve expensive equipment, fatigue, or technical workers. They are well suited to the examination of large numbers of samples, and since the poorest milks reduce first, a check-up at the farm may be made without delay.

While extensively employed in the dairy industry, the methylene blue reduction test has received more limited acceptance by milk sanitarians on this continent. Doubtless this is due largely to the feeling that the reduction test, since it does not always correlate exactly with the bacterial count, is not sufficiently reliable for official control. In view of the fact that there is no method available for determining with perfect accuracy the actual number of bacteria present, and of the evidence accumulating concerning the

* Read before the Laboratory Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 28, 1938.

Contribution No. 54 (Journal Series) from the Division of Bacteriology, Science Service, Dominion Department of Agriculture, Ottawa.

degree of error inherent in the counting methods commonly employed,^{10, 11, 15, 21, 22, 30, 31} this attitude becomes increasingly difficult to justify.

While the dairy industry is interested in the methylene blue reduction test chiefly as an indicator of keeping quality, it is recognized that in official milk control current interest centers upon the established general relationship between reduction time and initial bacterial content.^{16, 23} Although discrepancies between reduction times and counts are not infrequently due to errors in the counting methods employed, it should be recognized that there are various factors which tend to disturb this relationship.⁷ Many of these are uncontrollable and their importance in practice has yet to be established. There are good reasons for believing that the most important factor, and one which is controllable, is the sweeping of varying proportions of the bacteria to the surface with the rising fat globules. The extent of the error thus introduced increases as the reduction time is prolonged, and has resulted in the feeling that the test is not reasonably accurate beyond the 5½ hour period.^{23, 24} Where steps are taken to redisperse the fat globules and accompanying bacteria at intervals during incubation, reduction time is generally shortened, significant variations between replicate tubes disappear, and decolorization is uniform throughout the tube.^{3, 6, 7, 23, 27, 30} On the recommendation of Wilson,³⁰ a modified test, the chief feature of which is the inversion of the tubes every 30 minutes, has been adopted in England for the official analysis of graded raw milks.¹² Frayer³ and Johns⁷ have published data favoring the modified test, but Thornton^{26, 27} opposes its adoption on this continent on the grounds that the accuracy of the test is not significantly increased thereby, while the technic is complicated unduly. Although for-

merly contending that mixing at intervals will lead to more accurate results with good milks,^{23, 24, 25} Thornton²⁶ now states that "neither test greatly excels the other in accuracy, despite the greater variability displayed in the standard test which may lead to inaccuracy in evaluating an individual milk." This opinion is mainly based upon the high coefficient of correlation (0.94 ± 0.004) he reports for the two tests.

Although admitting that "the variability displayed by the standard test may lead to inaccuracy in the case of an individual sample," Thornton appears to overlook the fact that it is not the *average* for a *series* of samples, but the reliability of the values obtained for each *individual* sample, with which we are concerned. He also appears to overlook a point of fundamental importance in any discussion of the relative accuracies of the two tests. Whether regarded as an index of initial bacterial content or of keeping quality, the test will obviously be most accurate where it reflects the oxygen consuming activity of *all* of the bacteria growing in the milk. This can only be done where the bacteria remain uniformly dispersed throughout the milk, and we may regard this as the *true* reduction time. Under the standard technic, however, we actually measure the time required by the highly variable fraction of the total bacteria not swept to the surface⁹ to reduce the dye in the body of the milk. Any practicable modification of technic whereby a more uniform dispersion is maintained should yield results more nearly approaching the *true* reduction time and may consequently be regarded as more accurate than the standard test.

While the results with different samples are not strictly comparable because of variations in the interval between the last inversion and the preparation of the smears, the data in

¹ Average of triplicate tubes. Modified test—tubes inverted hourly
² 60 fields counted (individual cells)
 * Smear prepared at 4½ hrs.
 † Smear prepared at 11½ hrs.

Table I indicate that hourly mixing does bring about more uniform distribution of bacteria. It will also be observed that significantly larger numbers of bacteria are required to bring about reduction in the standard test (E), while there is less uniformity in such counts than in those at the moment of reduction in the modified test. Lastly, attention should be drawn to the wide differences in the ratios of standard to modified reduction times. Such differences have been found to be characteristic of milks from certain herds,⁷ and are related to differences in the intensity of creaming. While the limitations of the direct microscopic method are responsible for some discrepancies, the differences are sufficiently great to warrant the conclusion that the modified test reflects the initial bacterial content much more

accurately than does the standard test. Another way of comparing the accuracies of the two tests as a measure of bacterial numbers is to observe the correlation between the initial direct microscopic count and the reduction time. Data from 171 samples presented in Figure I indicate definitely less scatter with the modified method, particularly in the case of samples showing large numbers of mastitis streptococci. In view of the current interest in mastitis, this feature is deserving of consideration. In those areas where control work is confined to the detection of the poorest milks there will be little interest in the modified test. Where higher standards are set, the improved accuracy and shortened reduction time of the modified test should commend it. Since there is satisfactory agreement

FIGURE I

between inversion at $\frac{1}{2}$, 1, and 2 hrs.,⁸ a 2 hour inversion program would permit classification into 4 grades by observing the tubes after 2, 4, and 6 hrs.* This would avoid Thornton's objection that inversion of the tubes complicates the technic unduly.

Mention has been made of certain shortcomings of the methylene blue reduction test. To complete the picture, let us consider some of its specific advantages. Since a much larger portion

of milk is examined,[†] it avoids the serious errors frequently met with in the counting methods as a result of the uneven distribution of the organisms in the milk.^{9, 19, 30} Again, the clumping of organisms has little or no influence upon reduction time, while the plate count, and to a lesser extent the direct microscopic count, are seriously affected.^{15, 19, 28, 30} Finally, the reduction test is sensitive to the state of

* These grade limits correspond to average standard reduction times of 2, 5, and $8\frac{1}{2}$ hrs.⁸

† 50,000 to over 200,000 times as great as in the direct microscopic method and 1,000 to 100,000 times as great as in the plate count.

activity of the organisms,^{19, 30} which the counting methods fail to reflect.

With rare exceptions, milk sanitarians have thought of bacteriological quality exclusively in terms of numbers. Admittedly there is a definite relation between care in production and handling and the bacterial content. There is also a definite but less well recognized relation between cooling practices and the state of activity of the organisms. It has been shown^{19, 30} that the reduction test is sensitive to metabolic activity during the lag phase of growth, while the plate count is not. Few would contend that a sample was of equal quality at the beginning and end of the lag phase even though the count remained the same. Since faulty cooling practices are the chief cause of high count milks it seems only reasonable to regard the sensitivity of the reduction test to the state of activity of

the organisms as an advantage not possessed by counting methods. After all, the consumer is primarily interested in keeping quality, which is a reflection of both numbers and activity of the organisms. The employment of the reduction test in official control would therefore tend to place more emphasis upon the state of activity of the organisms, a feature which many believe has not received adequate recognition.

THE RESAZURIN TEST

There is considerable current interest in the resazurin test.^{1,2,4,5,13,14,17,18,19,20,29} The chief advantages claimed are: (a) it will furnish as much information after 1 hr. of incubation as will the older test after 5 to 7 hrs., and (b) it will more readily detect physiologically or pathologically abnormal milks.

While cognizant of its limitations, especially with low-count milk,^{19, 21} we

FIGURE II

FIGURE III

have chosen the Breed count as the basis for assessing the value of the resazurin test as an index of bacterial numbers. An attempt has been made to increase the accuracy by counting 80 fields. In both resazurin and methylene blue reduction tests the creaming error was minimized by inverting the tubes every two hours, until incipient reduction was noted.

It was expected that the reported sensitivity of resazurin to milks with high cell counts^{1, 17} would seriously disturb the correlation between resazurin number and count, but in our studies (Figure II) this appears to have exerted little influence. Instead, the correlation is poorest with milks showing the least change in resazurin color. Comparable data from the

modified methylene blue reduction test are presented in Figure III. While there is a considerable degree of scatter, it appears that the latter test indicates the initial bacterial content more reliably.

The available evidence suggests that, with certain samples, resazurin will react to high cell counts more readily than will methylene blue.* It will not, however, invariably detect such milks, as Ramsdell's data, as well as our own (Table II) clearly indicate. On the other hand, a larger proportion of milks with high bacteria counts will

* Since abnormally high cell counts are not infrequently encountered in milk from cows showing no definite evidence of mastitis, it may be open to question whether the condemnation of such milks by the resazurin test is justifiable.

³ Tubes inverted at 2 hr. intervals until incipient reduction noted

* Long chain streptococci preponderant

escape detection by the resazurin test. Microscopic examination of milks showing marked change in 1 hr., as recommended by certain workers^{1, 4} increases the diagnostic value of the test as regards mastitis, etc., but fails to compensate for the weakness just referred to.

In our studies of resazurin, observations were continued to the point of complete decolorization. Further analysis of the data disclosed a surprisingly close correlation between the time required to reduce resazurin to the pink stage and the methylene blue reduction time (Figure IV). Using this pink stage as the end-point, the incubation period is about three-quarters of that required to reduce methylene blue. When employed in this manner, rather than as a 1 hr. test, the resazurin test

appears to furnish a satisfactory index of bacteriological quality.

Whether or not resazurin will replace methylene blue remains to be seen. In spite of such shortcomings as sensitivity to light,^{4, 13, 17, 20} difficulty of obtaining satisfactory color standards,^{1, 13} difficulty experienced by some operators in distinguishing shades of color,¹ and lack of sensitivity to dormant organisms in well cooled milk,^{9, 17} several directors of plant laboratories^{1, 13} feel that the 1 hr. test may replace the methylene blue test for the grading of milk. Our own findings incline us to agree with Frayer⁴ and Ritter¹⁸ that the 1 hr. test is not sufficiently reliable for this purpose. When, however, incubation is continued to the pink stage, resazurin appears to be equally as reliable as methylene blue, while possessing an

FIGURE IV—RELATION BETWEEN METHYLENE BLUE REDUCTION TIME AND TIME REQUIRED TO REDUCE RESAZURIN TO THE PINK STAGE (261 MARKET MILKS)

important advantage in the shortening of the reduction period.*

Considerable further research must be undertaken before our knowledge of the chemistry of resazurin and its reactions in milk will be comparable to that concerning methylene blue. Until that stage is reached it seems best to defer final judgment concerning the place of the resazurin test in the field of milk control.

SUMMARY AND CONCLUSIONS

For routine testing of incoming supplies, the methylene blue reduction test has many advantages over the usual counting methods.

The accuracy of the test as an index of the initial bacterial content of the

better grades of milk is greatly improved where the organisms are redispersed by periodical inversion. Inversion of tubes every 2 hrs. yields results in good agreement with those from more frequent mixing.

The resazurin 1 hr. test does not indicate the bacterial content as reliably as does the modified methylene blue reduction test. The former places a larger proportion of high count milks in the highest grade. When incubation is continued to the pink stage, the accuracy of the test compares very favorably with that of the methylene blue test, while the reduction time is shortened.

The correlation between resazurin color and cell count is much poorer with market milks than with individual quarter samples. Many market milks with high cell counts fail to bring about a significant color change.

* When inverted every 2 hrs. to redistribute the bacteria, milks reducing methylene blue in 8 hrs. by the standard technic will on the average reduce resazurin to the pink in around 4 hrs.

NOTE: The author desires to acknowledge the helpful coöperation of R. K. Howson, B.S.A., in the laboratory studies, and to express his thanks to Dr. A. G. Lochhead, Dominion Agricultural Bacteriologist, for helpful suggestions in the preparation of this paper.

Experience of the Victorian Order of Nurses for Canada

With Cases of Pregnancy as Reflected by Case Records

J. T. PHAIR, M.B., D.P.H., F.A.P.H.A., A. HARDISTY SELLERS,
M.D., D.P.H., AND MARY FERGUSON, R.N.

*Chief Medical Officer of Health for Ontario; Medical Statistician,
Department of Health for Ontario; and Supervisor, Victorian
Order of Nurses for Canada, Toronto, Canada*

FOR some years there has been considerable concern among both official and voluntary health agencies in the matter of the higher-than-should-be maternal death rate in the Dominion of Canada. This concern has been manifested in a variety of ways. The lay organizations have on occasion become restless under what they describe as the failure of those officially placed to evolve a satisfactory solution of this problem; with the result that they have attempted to draw their own conclusions from the limited amount of factual information which has been available in this country.

Invidious comparisons have been made as between Canada and those countries in which midwifery practice is the vogue and there is a pronounced inclination to place undue emphasis on the presumed significance of certain

factors thought to be contributory to the high death rate.

The medical profession has been charged with an inadequate interest in the problem and it has been implied that such factors as unwarranted surgical interference, lack of adequate medical care, and the failure on the part of the profession to extend the maximum in the way of prenatal supervision have played a substantial part in bringing about this unjustifiable state of affairs. The necessity for the early establishment and continued maintenance of prenatal supervision has been emphasized to the extent that it is apparently regarded by many as a panacea for all the ills of the pregnant state.

The fact remains that the maternal death rate in Canada has been in the main unaffected by such efforts as have heretofore been directed at its lowering, and public concern in respect to this matter would appear to be justified.

Some 6 years ago, the Provincial Department of Health for the Province of Ontario sought the coöperation of the

* A preliminary report, read at a Joint Session of the Child Hygiene and Public Health Nursing Sections of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 28, 1938.

medical men of the province in an attempt to secure certain desired data in all cases in which death was associated with pregnancy. The supplying of this information was made obligatory by statute one year later. After a careful review of the data secured, it was felt that much might be gained by an attempt to secure specific information as to what happens to the 995 women out of every 1,000 who, following pregnancy, do not die. Actually, it was felt that little in the way of progress could be made until we were better informed as to conditions associated with what might be described as "normal" pregnancies.

The members of the Sub-Committee on Maternal Mortality of the Dominion Council of Health, appreciative of the difficulties of securing accurate information of this type, turned to the Victorian Order of Nurses for Canada, suggesting that an intimate statistical review of their records might be helpful. This organization, which is national in its scope, operates a highly desirable type of bedside nursing care in a large number of urban centers throughout Canada. Some 48 municipalities in the Province of Ontario alone are served by the Order and much of the service rendered is to those in need of nursing care during pregnancy. The average number of maternity cases annually attended by the Order during the last 5 years was roundly 12,000.

The committee was probably influenced in its decision to secure the help of the Order by the fact that for many years not only has the maternal mortality rate among those cases attended by the Order been approximately half that of the rate for the country as a whole, but also the neonatal rate has been uniformly lower than the official rate for the Dominion. The fact that these patients are largely cared for by physicians without any special qualifications in the field of obstetrical

practice; that with relatively few exceptions they are delivered at home; and that many of them come from an economic level below the average; has continuously intrigued the interests of those officially concerned with this phase of organized public health.

The Order when approached was appreciative of the opportunity to make a contribution to the possible solution of this problem and willingly agreed to undertake much of the expense associated with the study. The study includes approximately 10,000 case records, comprising all cases attended by the Order during the years 1935 and 1936 in the Cities of Ottawa and Toronto as well as in East York and York Township. All cases were included regardless of the number of visits or whether the period of viability was attained or not. At this date, the information regarding 5,049 cases has been tabulated.

While it is planned ultimately to make available a complete detailed analysis of the results of the entire study, it has not been thought wise on this occasion to do more than report briefly our findings to date, under appropriate headings.

ECONOMIC STATUS OF THOSE SERVED

It was found that the majority of those receiving nursing care from the Order were, as previously implied, in the lower wage earning bracket. As the family income was not noted on the report form, this deduction was drawn from the fact that the monthly rental for living quarters was in 22 per cent between \$10 and \$15; and in 20 per cent between \$16 and \$24. Only about 1 per cent were reported as paying over \$40 per month for housing accommodation.

This inference was further supported by the fact that the nurse, using a rather elastic measuring rod, reported the economic status as:

	<i>Per cent</i>
Comfortable	16
Supplied with the necessities of life..	41
In a state of poverty.....	15
No reliable data reported.....	28

The home supplied less than one room per person in 35 per cent of the cases and 1 to 1.5 rooms per person in 30 per cent. The home conditions, a term with many implications, were noted by the nurse as being good in 53 per cent, fair in 23 per cent, and poor in 5.5 per cent.

SIZE OF FAMILY

In 16 per cent the cases were primipara; in 18 per cent there was one previously born child, while in 18 per cent the family consisted of 5 members.

SOURCE OF CONTACT

It is the fixed practice of the Order to serve only those who have already contacted their physician, although it is not required that the original contact with the Order shall be through the physician. In fact, only in some 19 per cent of the cases did the request for service come from the physician in attendance. In the bulk of the balance, namely, 52 per cent, the patient herself or her family sought the service. Only in some 5 per cent of the cases was the case referred by the existing public health agencies.

These findings do not necessarily imply an absence of interest in the matter of maternal hygiene by the health personnel in those municipalities under survey but rather that this field has been considered to be the rightful prerogative of the Order. It has been said that this concession of the responsibility of insuring adequate nursing supervision during the periods of pregnancy and labor for those less financially fortunate, and its attendant obligations in the field of maternal and child hygiene, to a semi-official agency, has on occasion been too willingly made.

However, it is reasonable to presume that this criticism is unfounded and that the community public health nursing staff actually suggest, in many instances, that the contact be made by the family or physician instead of through official channels.

AGE

Five per cent of the cases were under 20 years of age; 24 per cent between 20 and 24 years; 27.5 per cent between 25 and 29; 21.5 per cent between 30 and 34; approximately 15 per cent between 35 and 39. These figures conform to the statistical data secured from other sources.

PERIOD WHEN CONTACT MADE

Much in the way of importance has been placed on the inadequacy of the prenatal supervision extended to those dying as the result of pregnancy. In the report of the Ontario study in 1934¹ only 41 per cent were said to have received adequate prenatal care. The extent of the supervision in the present series can be inferred in part from the time in months when the patient contacted the Order.

In 24.7 per cent the contact was made before the end of the 6th month of pregnancy; 19.6 per cent were made during the 7th and 8th months; and 42 per cent occurred during the 9th month; with 31.6 per cent within 2 weeks of confinement; some 9.2 per cent were first seen during labor.

TIME OF CONTACT WITH PHYSICIAN

The time when the contact with the attending physician was made might also be considered as indicative of the extent of the supervision given. The time of the contact with the physician need not necessarily be coincident with the date of contact with the nurse, in view of the fact that, as previously mentioned, the contact with the doctor must come first.

Twenty-six per cent had already informed their physician of their condition before the beginning of the 4th month of pregnancy, and an additional 26 per cent had seen him before the end of the 6th month. Ten per cent made their initial contact during the 8th, and 6 per cent during the 9th month. Six per cent called him during labor. In 17 per cent, the time of contact was not recorded.

The extent of the medical supervision is unknown. It is, however, a reasonable implication that a significant part of the sustained supervision was left to the nurse following her contact with the patient.

TYPE OF NURSING SUPERVISION

The scope of this supervision was recorded as being either grade 1, 2, or 3, dependent on the time of contact in months, the number of visits made, and the periods elapsing between such visits. It was reported as grade 1 in 807 cases, grade 2 in 1,772, and grade 3 in 1,749. In 714 contact was too late to permit of grading.

PLACE OF DELIVERY

Delivery naturally took place in the home in the vast majority of those served, only 12 per cent being hospitalized. This latter group comprises not only those who were found to require hospital care during delivery but also those who requested the Order to supply only prenatal supervision, having originally planned to be cared for during labor in hospital. In no particular age group was hospital care more prevalent than in the other.

CONDITION ON DISCHARGE

Six weeks' post-natal care is extended; the patient being then ordinarily discharged. The condition of the mother at the time of discharge was noted as being: good in 94 per cent of cases and poor in only 33 cases.

COMPLICATIONS OF PREGNANCY

These were divided into medical and obstetrical, major and minor.

Medical—major: In this group, data were available in 4,261 cases. Heart disease was reported in 22 cases, pneumonia and influenza in the same number, nephritis in 16 instances, high blood pressure in 30, diseases of the thyroid in 5, mental disturbance in 13, others in this group number 32, giving a total of 141 cases, or 3.3 per cent in which some significant complicating illness was present during pregnancy.

Obstetrical—major: Early toxemia—65 cases, early hemorrhage in 85, pyelitis and cystitis in 14, late toxemia in 130, late hemorrhage in 56, late vomiting in 48, other complications 9, being a total of 375, or approximately 9 per cent in which some major obstetrical complication occurred (data for 4,276 cases).

Minor Medical and Obstetrical: Anemia of pregnancy—90 cases, dental caries 1,390 or 30 per cent, upper respiratory infection in 100 cases, phlebitis in 40, abnormal nipples 169, hemorrhoids 20, varicose veins severe enough to be persistently troublesome in 1,106, constipation in 11, and others 21, being a total of 2,363, or 56 per cent of the 4,263 cases in which such information was recorded.

COMPLICATIONS OF LABOR

Malpresentation was recorded in 60 cases, placenta previa in 8, dystocia in 21, and shock in 15, retained placenta in 2.

The following general complications of labor were noted in those delivered at home. *e.g.*, laceration in 792 cases, severe hemorrhage in 62, abnormal placenta in 20, laceration and hemorrhage in 19, and hemorrhage and abnormal placenta in 6 instances.

TYPE OF DELIVERY

Delivery was spontaneous in 75 per

cent of cases, was manual in 2.2 per cent, instrumental in 10.5 per cent, and operative in 0.3 per cent (no data in 11.7 per cent).

PUERPERAL PYREXIA

Pyrexia was defined as a temperature of 100.4 or over on two successive takings, or a single reading on two successive days. Forty-nine of these had a temperature of 100.4–101° in the first 5 days; 25 had such an elevation of temperature for from 6 to 21 days; while 19 had a temperature above 101° in the first 5 days, and 21 were above 101° for from 6 to 21 days.

OUTCOME OF PREGNANCY

Of the 5,059 cases included in this study, 109 aborted, 108 had a miscarriage; 4,681 gave birth to a living infant, and in 158 cases the infant was born dead. In 15 cases the mother died; only 11 of these, however, could be considered as true maternal deaths.

INFANT DEATHS

Those responsible for the conduct of the program of the Order point with pride to the fact that the neonatal death rate of the infants of those attended by the nursing staff is measurably lower than the general rate for the country as a whole. In the group under review, it was under 26.9 per 1,000

live births, in contrast to the provincial rate in Ontario of 32.4.

MATERNAL DEATH RATE

The maternal death rate in the group for the two years in question was 2.4 per 1,000 live births, in comparison with the Ontario rate of 5.3. Five of the 11 deaths occurred in the age group 20–29; 4 among those from 30 to 39, and 2 in the age group 40–49.

CONCLUSION

In conclusion, might we say that while a study of this type may appear to permit of little in the way of conclusion being drawn, we believe that when the statistical analysis is completed the available data will assist materially in placing in the proper sequence some of those factors known to contribute to the maternal morbidity rate, and presumably the mortality rate, and in so doing will be of some value to those who might rightly be concerned with the task of finding some answer to that disconcerting question why in those countries in which the highest percentage of pregnant women are cared for by a physician during the period of labor, is there no lessening in the hazards of child bearing?

A Health Department Birth Control Program*

ROY NORTON, M.D., M.P.H., F.A.P.H.A.

*Assistant Director, Division of Preventive Medicine, North Carolina
State Board of Health, Raleigh, N. C.*

EIGHTEEN months ago the North Carolina State Board of Health became the first to sponsor a health department birth control program. The state has a total population of three and a half million people, over a million of whom are Negroes. Maternal mortality rates have been very high, as have also been the rates of birth and infant mortality. The data on infanticide and abortion are incomplete but competent observers estimate that these rates are too high.

Through a sympathetic attitude in medical and health matters the State Board's *Monthly Health Bulletin* has led the people to write letters presenting their problems and desires. In each of the last several years literally hundreds of underprivileged multiparous or organically diseased wives have written letters to the State Board of Health pleading for contraceptive advice—13 pregnancies and only 4 living children; 9 pregnancies in 11 years, and now suffering from heart trouble; 26 year old mother with 10th pregnancy and bedridden with cardio-renal disease; and so

on. These women have begged for release from the health hazards to which they are exposed by contraceptive ignorance. They all desire children but they prefer that the babies come in such numbers and with the conception timed for the best health interest of mother and offspring. They want to be better mothers with healthier babies and they feel that being able to say when and under what conditions babies shall come will promote the attainment of these worthy aims.

Fortunately, North Carolina has passed no statutory hindrance to physicians who desire to give contraceptive advice to their patients, and federal statutes do not prevent this. Most physicians, however, have not been adequately taught in medical school regarding their legal rights and limitations, and many have, until recently, considered it illegal to give birth control information. To all except a favored few of their patients, therefore, they have turned a deaf ear to requests for such information. Physicians have been almost as afraid of giving contraceptive advice as they have been with regard to abortion and narcotics, fearing that they might get into legal difficulties on a technicality.

The state has been particularly fortunate in having liberal minded social

* Read before the Health Officers Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 28, 1938.

and religious leaders and in having liberal colleges. There has been no organized opposition to the growing liberalism and public interest in behalf of the underprivileged among our people.

DEVELOPMENT OF PROGRAM

Local leaders have given approval and coöperation to the work of the two birth control clinics that have been operated in the state for several years. The first began in 1922 and is still active. Both of these clinics have gradually gravitated into a closer connection with the local health department, although they began under private sponsorship. The work of those more liberal minded and better informed physicians who have given birth control information to certain of their fortunate private patients has also been given general approval.

The North Carolina Maternal Health League was organized in 1935 as an outgrowth from the North Carolina Social Service Conference which in 1932 led a large group of state organizations that have formally given approval to birth control work. For 25 years the Conference has enlisted the active sponsorship and full coöperation of a great many of the state's best leaders in practically all lines of activities. For many years these leaders were active in promoting a better medical and health education program for mothers, but no organized effort toward the establishment of birth control clinics was made either by the Conference or its successor League. For 15 years Dr. George M. Cooper, Assistant State Health Officer, has handled the health education work and edited the *Monthly Health Bulletin* of the State Board of Health. In this connection he has become familiar with the problems and desires of thousands of our people in the state who have written to the State Board of Health for information and help, and he has also been active in

the Social Service Conference and the Maternal Health League work.

Early in 1937 a physician who was especially interested in seeing the public health value of the contraceptive program tested made an offer to the State Board of Health. This included the services for a year of demonstration work of a consultant nurse who had an excellent background of training and experience in organization work. The executive staff accepted this offer and the consultant was assigned to work in the Division of Preventive Medicine, of which Dr. Cooper is Director and in which the state maternal and infant health program is carried out. State Health Department sponsorship of local health department supervision of the giving of contraceptive advice for medical indications officially began April 1, 1937.

ORGANIZATION OF LOCAL PROGRAM

A letter was sent by the Assistant State Health Officer to the local health directors announcing the availability of medical and nursing consultant services for local health departments desiring assistance in the planning of programs for giving contraceptive advice for medical indications. About the same time a similar letter announcing these services was sent by the President of the Maternal Health League to the county welfare officers. The local health officers desiring these consultant services then made their requests to the State Board of Health. At the visit following such requests the nurse outlined the various local adaptations of a birth control program, the technics of birth control usually practised, the methods of selecting patients for the services, the cost of materials, the handling of patients and other similar problems. At this first consultation the health officer usually has arranged conferences between a few local medical and lay leaders and the consultant. If the

health officer then felt it advisable to try to organize a birth control service for his county or city the approval of the local medical society was requested. No request of the local health officer for medical society approval of the contraceptive program has been denied. Medical and nurse consultant services are then made available to those who are to be responsible for carrying out the birth control program of the health department.

OPERATION OF PROGRAM

It has been the policy to give contraceptive advice only to medically indigent mothers. Others are encouraged to go to their family physicians for proper advice. The method of selecting patients has varied according to local health department and medical society preferences. Referral has usually been by local physicians, the welfare department, or the health department medical and nursing staff. The patients have been served on strictly medical indications, and it has been found that these are sufficiently elastic to avoid the denial of service to those deserving it from the health department. In some health departments instruction is carried out altogether in clinics operated by the health officer or by local private physicians, in others the private physicians accept referral of patients for instruction and distribution of materials furnished through the health department, while in some others a large part or all of it is carried out through home visits by the public health nurses after investigation and approval by the health officer.

Considerable thought has been given to available contraceptive methods adaptable to a health department program. In most locations the sponge and foam powder technic has been the method of choice and only 5 clinics use an alternate method (diaphragm and jelly) in the health department work.

The sponge and foam powder technic has the great advantage that materials can be distributed and adequate simple instructions given without requiring a large investment of a physician's time. Careful records are kept of all cases so that an accurate estimate of its effectiveness can be compiled. Even if it should eventually be proved that the effectiveness of the method selected is less than that of the more intricate methods, it is believed that it will make possible the reaching of a larger number of mothers and thus eliminate many undesirable pregnancies which could not be prevented in any other way.

The health department birth control program has in each case been coördinated with the general maternal and infant health program. The encouragement of having larger families in selected cases and even enabling some couples hitherto sterile to have babies has been as much a part of the program as has the assistance in the prevention of conception wherever medical considerations have justified it.

RESULTS

The sponsorship of local health department contraceptive programs has been carried on quietly. There has been no fanfare, ballyhoo, or over-aggressiveness. Following the announcement of the availability of the consultant service, the difficulty has been to meet the requests from the local health officers, and to begin even to scratch the surface of this great problem. There has been no hurry. Approval by local practitioners has been insisted upon by the State Health Department before inauguration of the program. After 18 months, 56 clinics are operating in 50 of the 100 counties in the state. No attempt has been made to make the service immediately available to great numbers. We have no imposing statistics to offer but, in the short time of operation and with the small number

of patients served, those familiar with conditions know that the medical need and the public desire justify the beginning of the program. Patients and others in the community have expressed appreciation for the services. A total of 1,141 patients have been served during the first 18 months. Though it is still too early to reach an accurate conclusion regarding the effectiveness of the method selected, we have found so far only 6 cases in which it apparently failed and the mentality of 3 of these was very low. Only a very small number (12 out of 1,141) have reported personal objections to the sponge and foam powder on account of unpleasantness, discomfort, irritation, burning or pain. Eventual closer follow-up will undoubtedly show more failures and more cases of irritation, partly at least because of the general low average intelligence, and poor personal hygiene facilities available to the group served.

An interesting by-product of this health department program has been the changed attitude of the local practising physicians in the communities served. The doctors have had their attention called to the availability of desirable contraceptives and to the fact that they may legally advise their use. As a result a great many women not in the indigent group have been given contraceptive advice by their family physicians.

COMMENT

1. The need and desire for a health department birth control program in the state has been observed and for 18 months an organized official attempt has been made to meet this urgent medical need and this public desire.

2. In the progress of the program during this brief trial it is felt that working quietly and ethically, selection of patients from among the medically indigent wives for strict medical indications and insistence upon local medical approval for state sponsorship have each proved helpful.

3. The sponge and foam powder or some comparably simple method seems particularly suitable for use by those being given this preventive maternal health service through health departments.

4. A health department birth control program is an essential part of the maternity and infant public health service and the better selection of pregnancy risks should favorably affect maternal and infant morbidity and mortality conditions in the counties served. To preserve balance in a generalized public health program it is important continually to develop more nearly complete health education programs and to make available the necessary clinical facilities that serve to encourage or prevent conception according to medical indications.

Late-Lactose Fermenting Organisms of the Coli-Aerogenes Group*

NEWELL R. ZIEGLER, M.D.

*Department of Pathology, Bacteriology, and Preventive Medicine,
University of Missouri, Columbia, Mo.*

A NUMBER of investigators have reported the transformation of late-lactose fermenting organisms of the coli-aerogenes group to rapidly fermenting types by frequent sub-culture either in simple nutrient media or media containing lactose.¹⁻⁶ Such late-lactose fermenting organisms may belong to either the coli or aerogenes groups, as indicated by the Voges-Proskauer and methyl-red tests. Both indol negative and indol positive types are found. Such organisms have been isolated from the stools of both healthy people and of those ill with diarrhea, from a blood stream infection, and from water supplies. The acquisition of a normal rate of lactose fermentation appears to relate such organisms to the usual types of *B. coli* or *B. aerogenes*. Hershey and Bronfenbrenner,⁶ however, suggested, on the basis of reversion of a rapid-lactose fermenting variant to a non-lactose fermenting strain in a sodium succinate medium, that late-lactose fermenting organisms may not be identical with other lactose fermenting members of the colon group. Similarly, Stokes, Weaver, and Sche-

rago⁷ reported the conversion of late-lactose fermenting organisms (paracoli) to rapid-lactose fermenters and back to late-fermenting types. They concluded that the strains studied were variants of various members of the coli-aerogenes group. It seems clear, then, as Kriebel and others have suggested, that such organisms are as definitely related to fecal contamination as *B. coli* itself.

One is interested in the conditions under which the late-lactose fermenting types may be found in water supplies. It is a common experience that such organisms come to our attention chiefly in water supplies which almost satisfy the Treasury Department's standard, or in highly diluted material. Lewis² has given us an important key which appears to explain the occurrence of late-lactose fermenting organisms in water. He studied the phenomenon of dissociation in mutabile strains of *Escherichia* and *Aerobacter* by the use of synthetic media containing lactose. These non-lactose fermenting variants gave rise to lactose fermenting strains in a proportion of 1:100,000 when grown on nutrient agar. He called attention to the fact that fermentation of lactose depends upon the relative proportion of fermenting and non-fermenting cells present. He found that when a mixture of cells of a strain of Aero-

*Read before the Laboratory Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 27, 1938.

bacter was prepared so that it contained 10 per cent of rapid-lactose fermenting cells and 90 per cent of non-lactose fermenting cells it fermented lactose in 12 hours irrespective of the total number of cells in the inoculum. With only 1 per cent of lactose fermenting cells present, the time required for fermentation was increased to 36 hours. Since the delay in lactose fermentation was found to be independent of the total number of cells of the two types in the inoculum, and since rapidly fermenting members of the coli-aerogenes group are commonly present in much greater numbers in a polluted water than the late-lactose fermenting organisms, late fermentation would not be evident in water analysis until some of the volumes of water inoculated contain only one organism. The slow-lactose fermenting organism is unable to grow as rapidly in competition with one capable of utilizing lactose rapidly.

The fact that organisms of the coli-aerogenes group can vary in their ability to ferment lactose and that slow fermenting organisms may be trained to ferment lactose rapidly appears to be well established by the work of Kriebel and others. Little has been offered to explain this variability to lactose fermentation. Hershey and Bronfenbrenner⁶ and Deere, Dulaney, and Michelson⁸ have demonstrated a decreased production of lactase by such slow-lactose fermenting variants.

Karström⁹ has studied bacterial enzymes by a somewhat different technic in order to determine their function. He made use of cells grown on nutrient media to which various carbohydrates were added. These cells were washed, suspended in a suitable buffer solution in the presence of a specific sugar or alcohol, and the rate of acid production noted by titrating the acid produced at successive intervals. In this way he found certain differences in the kind and amount of enzymes

produced. On the basis of this data he classified enzymes as constitutive and adaptive. The constitutive enzymes were always produced regardless of the substrate on which the cells were grown. Adaptive enzymes were only produced by cells when grown on a medium containing the corresponding substrate; e.g., *B. coli* grown in a medium containing lactose produces lactase, as indicated by the rapid production of acid when such cells are washed and placed in contact with lactose in a buffer solution. By using this method, Karström demonstrated that the enzyme lactase was an adaptive enzyme in the strains of *B. coli* and *B. aerogenes* which he studied. Such an enzyme may vary in amount, depending upon the conditions for growth or for synthesis of protoplasm. I suggest a reversal of such a mechanism is involved in the production of late-lactose fermenting types of organisms. In a polluted water the concentration of nutrient material is usually too low to permit active multiplication of cells but certain conditions may exist which may cause a decrease of lactose activity even in the absence of cell multiplication. Hitchner⁴ reported the acquisition of rapid fermentation of melibiose at the same time as rapid fermentation of lactose was acquired by a slow-lactose fermenting strain.

Peterson,¹⁰ in our laboratory, has tested an indol negative strain of late-lactose fermenting organism to determine whether or not its lactase was an adaptive enzyme as is true for *B. coli*. This strain was isolated from the intestinal tract of an infant ill with acute diarrhea.* In this organism lactose fermentation was produced by an adaptive enzyme. The lactase response in the presence of ammonium salts was much slower than for *B. coli* and *B.*

* Culture was obtained from Dr. E. R. Krumbiegel, Milwaukee Health Department.

aerogenes. This is additional evidence of the relationship of a late-lactose fermenting organism to members of the coli-aerogenes group.

One may consider the pathogenicity of late-lactose fermenting organisms in much the same way as one would consider the pathogenicity of *B. coli* or of strains of *Aerobacter*. Feldman¹¹ has reported a ratio of 5:4 for the occurrence of *Escherichia-Aerobacter* infections of the urinary tract. She regards the *Aerobacter* infections as being more toxic than those due to *B. coli*. The author¹² reported the occurrence of unusually high agglutinin titers in patients recovered from gastroenteritis when tested with a strain of late-lactose fermenting organism.

The following is a striking example of the pathogenicity of a strain of late-lactose fermenting organism obtained in pure culture from the blood of a previously healthy adult male. This patient had been well until March 11, 1937. On the morning of March 11 he did not feel well. He observed a slight diarrhea and was without any reserve energy. He went to work, but headache and dizziness developed and became so severe that he returned home about 11 o'clock. Although he ate a sandwich, he had no desire for food. He promptly became nauseated and vomited. He became extremely ill and shortly before 1 P.M. his physician was called. His pulse was weak; his blood pressure was systolic 50 millimeters; diastolic 30 millimeters. At times his pulse was not discernible. He was placed in an ambulance and taken to a hospital. He remembered leaving home but recalled nothing further until after he had been in the hospital for a time. A blood culture was taken. Lymphocytes appeared to be absent from the blood and hemoglobin was above normal. The blood culture became positive on March 13. This was plated and several colonies were isolated. All were Gram-

negative, nonmotile, gelatin-negative, indol positive, methyl red positive and Voges Proskauer negative organisms, which fermented lactose only slightly in 5 days. Sucrose was not fermented. A stool specimen obtained on March 14 was plated on Endo's agar. The colonies which developed were almost all colorless and among these were many late-lactose fermenting organisms culturally identical with those isolated from the blood.

Blood was obtained for agglutination on the 3rd, 7th, and 18th days after onset. The first specimen of blood agglutinated the "homologous" organisms from the blood stream at a maximum titer of 1:50. The second specimen agglutinated this organism at a maximum titer of 1:100, and the third specimen agglutinated this organism at a maximum dilution of 1:500. A demonstration of a rising titer of agglutinins is now regarded as indicative of infection. In this case the isolation of the organism from the blood stream should leave little doubt as to the infectivity of this strain of late-lactose fermenting organism.

SUMMARY

1. Transformations of late-lactose fermenting organisms are discussed.
2. An explanation of the occurrence of late-lactose fermenting organisms in water supplies is suggested.
3. A mechanism for the production of late-lactose fermenting organisms is suggested.
4. The pathogenicity of a strain of late-lactose fermenting organism of the colon group is demonstrated.

Slow Lactose Fermenters in Water Analysis*

MAC HARVEY McCRADY, F.A.P.H.A.

Chief of Laboratories, Quebec Ministry of Health, Montreal, Can.

LATE in the spring of 1938, following a discussion by a few eastern laboratory workers on the advisability of including in the routine estimate of coliform organisms in water those coliforms isolated from primary lactose broth tubes containing only small amounts of gas, your referee was requested to determine, by means of a questionnaire, the trend of opinion on this question among laboratory workers in the United States and Canada. A questionnaire was accordingly prepared and submitted to about 30 laboratory workers who were presumed to be particularly interested in the subject.

QUESTIONNAIRE

Do you consider it advisable, in routine work, to include in the coliform estimate those coliforms confirmed from lactose broth presumptives in which there has been produced, after 48 hrs. incubation at 37° C.:

1. From unfinished or finished waters (coagulated, filtered, treated or filtered-treated, etc.):
 - (a) Less than 5 per cent of gas
 - (b) Less than 10 per cent of gas
2. From natural waters (unfiltered and untreated river, spring, well, lake supplies):
 - (a) Less than 5 per cent of gas
 - (b) Less than 10 per cent of gas

Twenty-five replies, the details of which are shown in Table I, were received.

It will be observed that 15 (Group 1) of the replies unqualifiedly favor inclusion, in the coliform estimate, of coliform organisms confirmed from every lactose broth tube containing gas, regardless of the amount.

A second group of 6 replies indicate that the laboratories concerned disregard certain lactose broth tubes containing small amounts of gas, because of their experience of failure to confirm the presence of coliform organisms from an extremely large proportion of such tubes. The implication is clear that were their experience of confirmation from tubes containing small amounts of gas more favorable, they would include the coliform organisms so confirmed in their coliform estimates.

One reply (Group 3) favors disregard of small amounts of gas only in those lactose broth tubes planted with natural waters.

Only 3 replies (Group 4) frankly express doubt of the sanitary significance of the slow lactose fermenters. One worker considers these organisms to be "attenuated" or "devitalized," to have little sanitary significance, and believes that they may safely be ignored. Another states that, in his experience, "When such slow lactose fermenters are found, even though they prove to be members of the coliaerogenes group, the data so obtained usually fail to agree with the informa-

Lakes & rivers

tion given by the sanitary survey. In our opinion these organisms probably represent attenuated forms and are not indicative of such recent pollution as to be of significance." The third replies: "Our opinion . . . is based on the insistence of our Bureau of Sanitary Engineering that laboratory findings including such coliforms do not agree with field studies and throw considerable doubt upon the safety of supplies known to be in excellent sanitary condition."

A few excerpts from certain of the replies favoring the inclusion of slow lactose fermenters in the coliform estimate are quoted:

1. We know that a predominance of extraneous organisms from whatever cause may exert an influence ranging from partial suppression to complete elimination of the coliform group. For this reason it seems advisable not to miss any opportunity to recover the group organisms remaining viable. . . .

2. From the point of view of fresh feces those specimens which contain coliform organisms which give less than normal amounts of gas are less normal than specimens which

give coliforms with orthodox gas production. I find that such forms do occur in fresh feces. Not usually in large numbers, it is true, but they do occur and occasionally in pure culture. In my work with long-stored feces, I have been impressed by the increase in the fecal suspensions of coliform organisms defective in their gas producing properties. It is my belief that in times of drought and in waters subject to stagnation this factor is of importance. . . .

3. If for certain classes of waters it is deemed advisable to give the results of the sanitary survey precedence over the bacteriological results in forming an opinion regarding the sanitary quality of a supply this might be done, but it should be accomplished in this manner and not by ignoring a predetermined section of the gas forming portions of the sample. Such a procedure of ignoring one section of the coliform organisms isolated (when we know that many factors other than attenuation diminish the amount of gas produced) would tend to nullify the science upon which the test is based. . . .

4. There is in my opinion no scientific reason for assuming that coliform organisms isolated from low percentage gas presumptives have any less sanitary significance than any other coliform isolations. . . .

5. We know little as to the cause of weak fermenters, whether it is due to attenuated strains weakened by purification processes or

if they are indicative of remote sources of pollution. It is conceivable that attenuated strains of coliform bacteria might become greatly rejuvenated under favorable conditions of environment. . . .

6. I think that quite often these traces of gas are of sanitary significance; for instance, we frequently run across a rather bad sample where the 1 c.c. or possibly the 0.1 c.c. portion may be typically positive, and yet one or more of the 10 c.c. portions may show less than 10 per cent of gas with all giving typically positive results on the partially confirmed test. . . .

7. We have good reason to believe that chlorination, storage, the presence of other organisms (particularly *Pseudomonas*) may delay or reduce gas production by typical strains of *E. coli*. Consequently, I feel that the amount of gas produced in primary lactose broth is not a very good indication of the presence or absence of significant members of the colon-aerogenes group. . . .

It is evident that the great majority of the laboratory workers replying to this questionnaire consider slow lactose fermentation to be of possible sanitary significance. Although the question submitted is not one that must necessarily be decided by a majority vote, the weight of experience represented by those who favor including these organisms in the coliform estimate is impressive.

DISCUSSION

The question of the sanitary significance of the presence in water of coli-like organisms that produce small amounts (5 c.c. or 10 c.c.) of gas in lactose broth, upon incubation at 37° C. for 48 hours, has long been the subject of occasional informal discussion by laboratory workers; but in general these slow lactose fermenters have been accepted as genuine members of the coliform group of indicator organisms. The present *Standard Methods of Water Analysis*,¹ for example, includes such organisms in the coliform group as therein defined.

Since it is the usual practice to leave to the control authority the appraisal of

the sanitary significance of the presence in a water of *any* organism of the coliform group, difficulties arising from contradictory evidence furnished, on the one hand, by the laboratory and, on the other, by the field survey of the supply, are usually (although, unfortunately, not always) readily adjusted.

It is well known that coliform organisms frequently derive from sources unassociated with dangerous pollution, such as multiplication in sediments in mains, on wood, on other material of a vegetable nature, on tap washers, and from virgin soil, that such organisms are frequently atypical in character and that many of them are slow lactose fermenters. When, therefore, the cause of an excessive coliform density is determined to be other than that of access of pollution to the supply, the coliform report is simply ignored.

But is there reasonable justification for dismissing as of no sanitary significance *all* instances of slow lactose fermentation? One of the principal arguments favoring this course is that slow lactose fermentation is caused by "attenuated" organisms which have become so "devitalized" that they have lost their sanitary significance. This argument has been so frequently advanced that it deserves particular attention. In the first place, it perhaps will be admitted that the sanitary significance of the presence of coliform organisms in a treated, filtered, or filtered-treated water is ordinarily quite different from that of their presence in a natural water. Coliform organisms in a natural water serve usually as an indicator of the presence of human, animal, or soil pollution; and, depending upon the further indications furnished by the field survey of the supply, greater or less significance is attached to their presence. When a treated, filtered, or filtered-treated water is examined, however, since it is usually known that the original raw water

was polluted, the coliform estimate serves ordinarily, not as an index of pollution that may be more or less dangerous, but rather as a measure of the destruction or elimination, by the treatment, of associated disease organisms. Here there can be no question of tolerance—if the treatment is satisfactory; practically every disease organism of the raw water will have been eliminated and, by the same token, practically every coliform organism will have been eliminated. There exists no satisfactory evidence that slow lactose fermenters are more resistant to treatment than are typhoid or dysentery organisms; nor may it be contended that a treatment which reduces the gas production of a coliform organism 95 per cent necessarily deprives the typhoid bacillus of its pathogenicity. If, therefore, coliforms of *any* type persist in a treated water, and if their presence cannot satisfactorily be explained, the conclusion is inescapable that disease organisms may also persist in the water and that the treatment, therefore, has not been satisfactory.

Turning now to the question of the significance of slow lactose fermenters in natural waters, it must be admitted that the experienced water bacteriologist is inclined to regard the presence of these organisms with some measure of tolerance, not because they are so attenuated that associated disease organisms may be considered to be deprived of their pathogenicity, but because they are encountered with some frequency in relatively unpolluted soil, in sediments in mains, and on plants. On the other hand, it is well known that the presence of other organisms may reduce or even prevent the production of gas by coliform organisms in the lactose broth tube. In a recent study, in the Quebec laboratory, from 144 primary lactose broth tubes which contained only a bubble of gas after

48 hours of incubation, and which eventually yielded positive confirmations, coliforms that produced 5 per cent or more of gas in *secondary lactose* were isolated from 108, or 75 per cent. Rejuvenation of the organisms may have been responsible for some of this increase in gas production, but it must be remembered that the primary lactose broth is, itself, a rejuvenating medium.

Slow lactose fermenters have been shown by Parr⁴ to occur in fresh feces, sometimes in pure culture. Since he finds that they occur occasionally during periods when the normal intestinal function is impaired, the presence in water of certain slow fermenters may be of more than ordinary sanitary significance. Parr⁵ reports further an increase in the proportion of this type of coliform in feces that have been subjected to storage. It is evident therefore, that since the true slow lactose fermenters found in water may have derived from either fresh or stored feces, their presence, even in a natural water, cannot always be considered of no sanitary significance.*

CONCLUSIONS

Since the coliform density of a filtered, treated, or filtered-treated water is a measure of the effectiveness with which the treatment has eliminated disease organisms from the water, it is reasonable to attribute equal sanitary significance to the presence in such water of either typical or atypical coliform organisms, slow fermenters or rapid fermenters.

Slow lactose fermenters are found,

* In the above discussion, no reference has been made to such sources of error as inversion, during sterilization, of lactose to dextrose, and the presence in the broth of entrained air. These may readily be eliminated by exercising care when sterilizing lactose broth, and by incubating the tubes before use overnight, discarding those in which air bubbles are formed. Storage of fermentation-tubes at moderate, rather than very low temperatures may reduce the difficulty caused by entrained air.

although in small proportion, in fresh feces, in greater proportion in stored feces, and occasionally in discharges from cases of gastrointestinal disturbance; the presence of these organisms, even in *natural* waters, therefore, cannot always be dismissed as of negligible sanitary significance. Furthermore, since other organisms contained in the sample may reduce the amount of gas produced in lactose broth by typical coliform organisms, the volume of gas produced cannot be accepted as a sure indication of the type of organism present.

The replies to a questionnaire received from 25 laboratory workers of considerable experience of bacteriological water examination revealed that 15 of these workers favor unqualifiedly the inclusion of slow fermenters in the coliform estimate; 6 apparently favor including the slow fermenters, although in practice they do not attempt isolation from primary lactose broth tubes because in their experience coliform organisms are very rarely isolated from

such tubes; 1 favors including the slow fermenters isolated from filtered and treated waters but not from natural waters; and only 3 frankly express doubt of the sanitary significance of the slow lactose fermenters.

It is evident, therefore, that the great majority of the laboratory workers are opposed to excluding slow lactose fermenters from the coliform group of organisms. In view of the various facts and arguments that may be adduced to support their position, it is suggested that, until sufficient evidence to the contrary is presented, water laboratories are well advised to include, in their routine coliform estimates, *all* coliform organisms confirmed from primary lactose broth.

Slow Lactose Fermenters in Water Analysis*

ANNA DEAN DULANEY, PH.D., AND E. F. SMITH

*Department of Bacteriology, University of Tennessee;
City Laboratory of Memphis, Tenn.*

IF sanitary importance is to be attached to the finding of slow lactose fermenting, coliform bacilli in water proof of either their close relationship to accepted fecal bacteria or of their etiological rôle in disease must be offered.

We have been interested in slow lactose fermenting and atypical organisms of this type since Dr. Michelson and I^{1,2} isolated *B. coli* mutabile in high percentage from stools of very young babies suffering from an epidemic diarrhea during the winter of 1933-1934. These were the only bacteria consistently demonstrated in cultures from various sources—namely, feces, blood stream, pus from ears, and intestinal contents and heart blood at autopsy. We were very reluctant at the time to assign an etiological rôle to these organisms and we have never felt that the question as to whether they were the responsible agents of disease or whether they represented a marked alteration in the fecal flora as a result of physiological disbalance could be settled. Endo plates spread with fecal suspensions of these babies yielded 90 per cent or more of these organisms and this finding was obtained in 67 per cent of the affected babies.

At that time we also examined stools from normal babies and found the same type of organism in 12 per cent of cases—a finding which accentuated doubt regarding their ability to initiate disease. Since then, we have isolated this curious mutating organism only rarely from stools but we found that slow lactose fermenting and atypical coliforms are often present in the feces of normal and sick babies and adults. It has been our observation that such organisms are more numerous in stools from patients with diarrhea than in stools from normal individuals on stable diet.

In a series of 400 stools approximately 20 per cent were found to contain slow lactose fermenting organisms. We have usually found these organisms in small numbers, but in some specimens they have constituted from 10 to 50 per cent of all colonies. When colorless colonies from Endo's plates were transferred to Russell's Double Sugar agar, a paratyphoid reaction was obtained which was at times misleading. In most cases these slow lactose fermenting organisms have produced acid and gas in lactose broth after 2 to 5 days, though some strains required longer periods of incubation. Accelerated ability to ferment lactose usually followed their daily transplantation to this medium. Saccharose fermenting *Escherichia coli*, *Aerobacter acrogenes*, and intermediate

* Read before the Laboratory Section of the American Public Health Association at the Sixty-seventh Annual Meeting at Kansas City, Mo., October 27, 1938.

types have been identified. Intermediates have been found often enough to warrant them a place among the accepted fecal flora. We well realize that statistical data regarding the incidence of slow lactose fermenting or any other type organism found in feces, or the distribution of types means little, for we have obtained entirely different pictures on plates streaked with diluted fecal specimens from a single individual at different times.

The finding of slow lactose fermenting bacilli in feces has been reported by many workers. They have been regarded as the cause of diarrhea by some, evidence resting on their consistent presence in large numbers in feces of individuals affected. The variation which occurs from time to time in feces of individuals in normal health and on stable diet has been emphasized by Parr.³ He uses the term "fecal-flora-crises" to designate the distortion or temporary elimination of the coli-intermediate group picture. The fact that such a crisis may occur in the feces of normal as well as in diseased individuals makes him doubt the etiological significance of such atypical bacilli. All must admit that the pathogenic properties of these atypical coliforms is very hard to prove. Even their demonstration in large numbers during disease does not rule out the possibility that they may be secondary in character.

Occasionally members of this group are isolated from sources where their etiological rôle cannot be questioned. During the past 3 years we have obtained 10 strains of slow lactose fermenting coliforms from sites other than the intestinal tract. Nine strains came from urine (cystoscopic specimens) and one from the spinal fluid of a child suffering from meningitis. All of these belonged to the *Escherichia* group.

We have found that approximately 50 per cent of the fecal specimens

studied by us contained aerogenes organisms. In some specimens these organisms were absent or few, while in others they were the dominating type organism, and Endo's plates from other fecal samples showed only aerogenes colonies. There seems to be considerable variation in the reported incidence of aerogenes in feces (Brown and Skinner,⁴ Tonney and Noble,⁵ Breed and Norton,⁶ Gray,⁷ Parr⁸). The majority of fecal specimens studied by us have come from hospital wards which may have modified our findings. Aerogenes organisms are only occasionally pathogenic. We have isolated typical bacilli of this type from urine obtained by cystoscope and in one case we demonstrated this organism in 3 successive blood cultures from a patient suffering with a septicemia following a cholecystitis. In a recently studied diarrhea slow lactose fermenting aerogenes organisms were isolated in large numbers from feces at different times. No pathogen was demonstrated. Mucoid coli colonies (Theobald Smith⁹) are found on Endo's plates and it is often impossible to distinguish these from colonies formed by the aerogenes group. If mucoid colonies are fished at random, a good proportion of these will fail to grow in citrate and upon further study will be found to be *Escherichia coli*. These colonies are more frequent on Endo's plates incubated for longer than 24 hour periods.

Recently we became interested in the question of slow lactose fermenting bacilli which might be isolated from waters. We were primarily interested in the incidence and type of organism from such sources. For this study we used waters sent into the West Tennessee Division of the State Public Health Laboratory. Preliminary observations showed that slow lactose fermenters and atypical coliforms could be isolated from polluted and unpolluted waters. This is not a new observation—

Koser's ¹⁰ series of papers have included observations on such organisms found in water. *Escherichia-Aerobacter* intermediates have also been isolated from water by Lewis and Pittman,¹¹ Ruchhoft¹² and his associates, Gray,⁷ Poe,¹³ France,¹⁴ Parr and Caldwell.¹⁵

The series of cultures to be described were all isolated from "negative" waters—waters examined according to the procedure recommended by *Standard Methods* and showing no gas in any of the lactose broth tubes after the usual 48 hour incubation period. A pooled sample from several tubes was diluted and spread on dry Endo's plates. Colorless or colored colonies suggestive of the coliform group of organisms were fished to lactose broth. When fermentation of the lactose broth occurred these cultures were inoculated to Endo's plates and colonies fished to Russell's Double Sugar agar. This culture was subjected to two or three subsequent platings and the final Russell's Double Sugar Agar culture used for inoculation of various media.

These waters (300 in number) came from various sources. Private and semi-private wells in Memphis and public and private wells in Western Tennessee were represented. Three samples were from swimming pools and these were the only treated waters studied. All samples had been collected by trained persons. The interval between the time of collection and inoculation of lactose broth varied from a few hours to 24 hours. The samples from local wells reached the laboratory in an hour or so—those from out of town were usually sent in by special delivery and were not in transit over 24 hours. All specimens were un-iced.

Thirty-nine, or 13 per cent, of the 300 waters contained slow lactose fermenting organisms, "slow lactose fermenting" in that the initial 48 hour growth in lactose broth did not indicate their presence. Approximately 100

strains were isolated but when several of these from one water were of the same type, only one was counted. In most cases the colonies on Endo's plates were abundant, thus suggesting that the organisms had originally been present in the water in fair numbers. These organisms were Gram-negative non-sporulating bacteria producing acid and gas in lactose broth in 1 to 5 days after reinoculation from Endo's agar. Three strains required periods longer than 5 days. Small amounts of gas were usually produced in lactose broth. In most cases a paratyphoid reaction was given on Russell's Double Sugar but in a few instances the reactions were typical of coli.

The distribution included 18 members of the *aerogenes-cloacae* group as judged by lack of indol formation, negative methyl-red, positive Voges-Proskauer reactions, and abundant growth in citrate medium (made according to Koser's formula). Of these organisms, 3 liquefied gelatin. These may have been degraded *aerogenes* (Parr³) or *cloacae* types. All fermented cellobiose and were uric acid positive. Two strains were atypical in that indol was formed.

There were 19 methyl-red positive and Voges-Proskauer negative strains, of which 4 formed indol and grew in citrate medium. Fifteen cultures were indol negative and of these 12 were citrate positive and 3 citrate negative. All but one (an indol negative strain) produced acid and gas in cellobiose. This latter group of organisms would be classed as colon-*aerogenes* intermediates. No typical coli organisms were isolated. We are inclined to regard the intermediates which were indol negative, methyl-red positive, Voges-Proskauer negative and citrate positive as belonging to the *aerobacter* group while the strains which were indol positive, methyl-red positive, Voges-Proskauer negative and citrate positive

would seem to be more closely related to *Escherichia coli*.

No correlation between the source and finding could be established.

The question arises—do such data have any sanitary significance, or are they to be classed as merely interesting and yielding further information regarding the wide distribution of slow lactose fermenting coliform organisms?

As is well known, these atypical organisms may often complicate the confirmatory phase of water examination. An example is offered by one water on our list which is from a series examined monthly. Several times during the past year some of the lactose broth cultures have shown small amounts of gas, and atypical coliform organisms were demonstrated on Endo's plates and in lactose broth subsequently inoculated. Most tests were satisfactory but from these "negative" cultures we isolated the same or closely related organisms. Various factors—seasonal, quantitative, dissociative—may explain the detection of these organisms by routine methods at times, and the failure of detection at other times. Failure of detection by routine methods by no means indicates that they are not present.

Recently, water-borne epidemics of gastroenteritis have been reported which stimulate interest in the question of their potential pathogenicity (Veldee,¹⁶ Ziegler,¹⁷ Pharris, Kittrell, and Williams¹⁸). Ziegler¹⁶ isolated cultures from feces of patients during one of the epidemic periods which were identical in cultural reactions with those found in the city water supply at a time when typical *B. coli* were not demonstrated.

We have no history that any of the waters used in this preliminary study was ever suspected of causing an outbreak of gastroenteritis. Assuming that such occurred, how much significance could be attached to the presence of these organisms—even in large num-

bers—in the absence of fecal coli? One of two admissions must be made—they indicate fecal pollution, sufficiently recent to be significant, or, these organisms are alone capable of producing disease.

How may we determine the fecal or non-fecal nature of these organisms by procedures available in the usual laboratory? What is to be our criterion of pathogenicity?

The majority of these coliforms are intermediates. We have isolated organisms from feces which give identical cultural reactions, but shall we consider them truly fecal bacteria? Carpenter and Fulton¹⁹ found that 13.3 per cent of coliforms isolated from human feces fell into the intermediate group and they conclude that they have sanitary importance. A table in a recent paper by Parr²⁰ indicates that 7.7 per cent of fresh fecal specimens contained these organisms and that this incidence was increased upon storage. His table shows that over half of the intermediates encountered in fresh feces and approximately one-third of those in stored feces were indol negative, methyl-red positive, Voges-Proskauer negative, and citrate positive. It is interesting that 12 of the 39 slow lactose fermenting strains isolated from water fell into this group.

The origin of these intermediate organisms presents an intriguing question. Are they variants—stable or unstable—of better recognized forms? In our laboratory, Michelson² has found that citrate using strains may arise from non-citrate using *B. coli* mutabile. When these organisms were subjected to prolonged growth in lithium chloride broth and later spread on Endo's plates, some colonies formed mucoid papillae which yielded aerogenes-like organisms as regards their methyl-red, Voges-Proskauer and citrate reactions. He was not able to produce this phenomenon with orthodox *Escherichia coli*.

In conclusion, we feel that we must recognize the widespread distribution of such coliform organisms in untreated waters and in waters of apparently satisfactory sanitary state. They may or may not be detected in routine examinations. This finding should invite caution as to interpretation of their presence at any time. The results from sanitary surveys should be carefully applied and such data correlated with bacteriological findings. At the same time we must recognize that their non-fecal origin has not yet been proved and all information regarding their potential pathogenicity should be carefully accumulated and evaluated.

ARMY MEDICAL LIBRARY NEEDS NEW BUILDING

SOMEWHAT apart from the row of magnificent new government offices in the nation's capital stands a rather decrepit old red brick building. To its dingy halls come the world's foremost medical scholars. They come to consult and examine medico-literary treasures that can be found nowhere else. They come to delve into the history and tradition of medicine, to search for valuable information that will contribute to human welfare. And in seeking and finding this material, they gain not merely knowledge, but inspiration.

In this venerable structure, erected in 1887, is housed the Army Medical Library and Museum. Here is the largest collection of medical books in existence, nearly a million volumes. Here are 450 of the only 600 known medical incunabula, including more first editions than in any other library. Here are ancient documents, one dating from 1467, and numerous rare manuscripts of inestimable value.

This priceless collection of medical literature deserves better quarters. So inadequate is the present building that many books must be stored in the basement. Manuscripts, records, and books that are irreplaceable are exposed to the danger of fire and the hazards of dust, dirt, and decay.

In 1919 a site for a new building for this notable library and museum was acquired on the grounds of the Army Medical Center in Washington. Despite numerous requests and recommendations, Congress has never seen fit to make the necessary appropriation for a suitable edifice. At the last session of Congress, a building costing \$3,750,000 was authorized, but no funds were actually appropriated for the purpose.

This relatively modest appropriation must be made by the present Congress. When the War Department has requested the funds, if it has not already done so, every physician and sanitarian should actively support this important measure.

The Army Medical Library and its indispensable *Index* were once characterized by the late Dr. William H. Welch as America's greatest contribution to medical science. Although established in 1836, the development of this library and of its outstanding services were due largely to the genius of Dr. John Shaw

Billings, one of the founders and early presidents of the American Public Health Association.

This Association urges, therefore, favorable consideration by Congress of an adequate appropriation for the world's foremost library devoted to medicine and public health, in order that this leading scientific institution may be provided with proper facilities for its invaluable collection of medical literature, and also so that it may serve physicians, scientists, and public health workers even more efficiently than in the past.

HENRY F. VAUGHAN, DR.P.H.—AN APPRECIATION

IT is seldom that a health officer is more signally-honored than was Dr. Henry F. Vaughan of Detroit at the testimonial dinner on January 12, under the auspices of the Detroit Department of Health. Dr. Vaughan has completed twenty-five years of service in the Department, first as an employee of the Division of Sanitation and, since 1918, as Commissioner of Health.

The group which participated in this recognition was significant, not only because of its size—1,050 people were assembled in the Masonic Temple for dinner—but because of the great variety of local individuals and organizations which were represented as a testimonial to the leadership of Dr. Vaughan during his quarter century of service. An illuminated chart comparing the death rates in Detroit in 1913 and 1938 was eloquent testimony to the changes which have taken place in this industrial center where for two decades and more the profession has become accustomed to look for a superlative example of public health administration. Those in attendance could not fail to note the generous credit which Dr. Vaughan gave to his colleagues for the advances which Detroit has made in its health program. It was a subtle revelation of the underlying reason for Dr. Vaughan's undisputed leadership.

Some health officers seem strangely reluctant to allow demonstrations of public approval of their services. Of course it is quite conceivable that these exhibitions might run beyond the limits of proper professional ethics; yet when a public expression is so sincere and spontaneous as was the case in Detroit, it must be conceded that it does a community good to recognize the devoted public service of all such soldiers of the common good. The Association joins with Detroit in congratulating Dr. Vaughan and his distinguished staff.

EQUINE ENCEPHALITIS IN MAN

ONE of the most interesting as well as important medical events in 1938 was the outbreak of equine encephalitis in several parts of the country, notably in New England. In Minnesota an epidemic in horses began in 1934 and the disease was very prevalent in 1937. In New England the outbreak began in Massachusetts in August, 1938. Important as this disease has been from the economic standpoint, the great interest which attaches to it is due to the fact that for the first time there was clear proof of its transmission to man. At the meeting of this Association in Kansas City a paper was read by Dr. Feemster,¹

who gave the details of 8 of these cases and discussed the situation fairly completely. As he said, these 8 cases in Massachusetts, are the first human infections definitely proved to be due to the equine virus. "An entirely new public health problem has been opened up and the equine disease assumes an added importance."

Shortly afterward two papers appeared in a single issue of the *J.A.M.A.*,^{2,3} one reporting 6 cases of human encephalitis which occurred in September, 1937, all in farmers, 5 of whom had been in contact with sick horses. The blood serum of 3 of these patients neutralized the Western strain of equine encephalitis. The authors state that as far as known this was the first time that neutralization of the equine virus by human serum had been found. Both of these papers discussed at some length the agency of insects, especially varieties of mosquitoes, in spreading the disease among horses, some observations concerning which had been made as far back as 1933.

Now we have a report from the Harvard Medical School⁴ on the occurrence of equine encephalomyelitis in ring-necked pheasants on range. The authors suggest that the horse plays only a minor part in the spread of equine encephalomyelitis and that the chief agents in its dissemination are migratory birds. They are inclined to the belief that the term "equine" is misleading as the disease is probably an avian infection, and doubt whether the horse or other domestic animals play any essential part in the perpetuation of this disease. "It may be only under accidental circumstances or when the infection arises to a certain level that it overflows and becomes a serious problem as regards the horse and even the human being."

In his address at Kansas City, Feemster told of the isolation by Fothergill and Dingle of the Eastern type of virus from a pigeon taken from an area in which the horse disease had been prevalent and where these birds had been dying in unusual numbers during the summer of 1937. This observation has now been published in full.⁵ All of the mice injected intracerebrally with both the filtered and unfiltered material died in 48-96 hours with symptoms similar to those of mice infected with equine virus of the Eastern variety. The identification of the pigeon virus was determined by the intracerebral injections of guinea pigs which had been immunized against the Eastern and Western varieties of the virus, and in normal controls.

The writers concluded that this work proved that the virus from this pigeon was that of the Eastern variety of equine encephalomyelitis, the disease having been "spontaneously contracted in an area where equine encephalomyelitis was prevalent among horses." The susceptibility of pigeons was demonstrated as early as 1933 by Giltner and Shahan,⁶ and in 1935 Ten Broeck, Hurst, and Traub⁷ suggested that pigeons might be the host reservoirs of this virus. A number of other observers in this country and in Europe have shown the susceptibility of various birds to the equine virus, including ducks, geese, hawks, black birds, and some others.

That there was a wide field open for study goes without saying. A very recent report⁸ is that epidemics of encephalomyelitis have broken out in the northern part of South America. Material has been sent to the Lederle Laboratories where experiments are now going on. The symptoms of the disease resemble those from the eastern outbreaks of the United States, but it is certain that the virus is significantly different from either of the two known American strains. The Venezuelan strain is immunologically different from either the Eastern or

Western Forms which we know here, but a remote relationship is suggested between the Eastern and Venezuelan strains.

GROWING PAINS

IT is an interesting coincidence that two extensive studies of so-called "growing pains,"* one in England¹ and one in America, should have been published almost simultaneously. Hawksley,¹ though regarding the name "growing pains" as very unsatisfactory, has found that "In spite of the challenging name of this condition it is thus perhaps the most suitable as, evading all concrete questions of aetiology, it describes a condition which is common in the growing human being." For a long time it has been taught almost universally that growing pains were an indication of rheumatism and that children suffering from them were in danger of development of cardiac lesions.

In a discussion before the American Rheumatism Association, Shapiro,² of Minneapolis, made the statement that, in from 8 to 50 per cent of children considered as rheumatic, the condition has been diagnosed on the basis of pain in the extremities alone. At the Lymanhurst Health Center an analysis of the histories of 100 patients with well developed rheumatic heart disease showed that 84 per cent had a definite history of a major attack of rheumatism—either rheumatic fever, or chorea, or both. Of the remaining 16, in practically every instance while there was no history of a major attack of rheumatic infection there was definite evidence of a long continued rheumatic infection.

At the same clinic a follow-up study, continued for 3 years on 200 children who complained only of leg pains, failed to show evidence of chronic rheumatic infection. They are in general good health and none of them have developed chronic heart disease.

T. Duckett Jones, of Boston, in discussing these findings, said, "the so-called growing pains in a child, without a frank history of previous rheumatic fever, do not frequently occur with other manifestations of rheumatic fever or a tendency to develop subsequent rheumatic heart disease. . . . The insidious or asymptomatic development of rheumatic heart disease in children is uncommon but in the young adult it is observed. . . . Mild to severe acute illness is almost invariable, and vague syndromes rarely exist."

Nazum, speaking of how prevalent the belief was that growing pains in children meant rheumatic fever, said that 3 of 6 current medical textbooks he

* Seham and Hilbert attribute the use of the term "growing pains" to Duchamp about 100 years ago. *Am. J. Dis. Child.*, 46:826, 1933.

examined laid stress on the importance of the history of growing pains in arriving at a diagnosis of rheumatic fever. In real rheumatic infections, approximately 75 per cent of children develop clinical evidence of heart lesions, and it is generally believed that every child with rheumatic fever suffers some damage to the heart, about 75 per cent of them having such a degree of inflammation as to produce real damage to the valves or the heart muscle, or to both.

In England (1936) Sheldon¹ analyzed 189 cases of growing pains in the Great Ormond Street Hospital and, after following up for 4 years, found only two who had developed rheumatism with heart lesions and none of them showed chorea. He pointed out that there was no evidence of the histo-pathological changes characteristic of acute rheumatism in growing pains, and that there is no relation between growing pains and sore throats.

In a further series of 24 cases of growing pains followed by Sheldon for 18 to 36 months none developed rheumatic manifestations, making a total of 213 cases of growing pains carefully followed, in which carditis developed in less than 1 per cent.

Of 1,000 children in London and Birmingham seen over 10 years, all those with a history of growing pains were especially studied, and at the Great Ormond Street Hospital, 115 cases of growing pains were subjected to special examinations and 64 of them were followed up after a lapse of 4 years. These children gave a variety of symptoms which are more or less characteristic of such cases, but none of them have shown any evidence of cardiac rheumatism. Taking the cases followed by Sheldon for 4 years with these 64 we have a total of 253 children, only 2 of whom, or less than 0.8 per cent, have developed rheumatic carditis.

The conclusions from these two studies, one in England and one of this country, are that the syndrome of growing pain is not related to rheumatic fever or sub-acute rheumatism and does not provoke rheumatic carditis.

An interesting discussion developed in this study—Does growth of itself produce pain? Shapiro states that he has consulted a number of investigators who are interested particularly in the study of growth, and tried to find out whether or not normal growth in itself might produce such symptoms as are known as growing pains.

No one would commit himself. There are suggestions, however, growing out of the examination of the 115 children mentioned. "There is a frequent history of colds and coughs, vasomotor instability, signs of vague ill health, such as lack of increase in weight, which of itself shows that the pain is not caused by growth. The most common cause was found to be minor orthopedic deformities. Psychological maladjustment was common and "many cases suffered from over-anxious parents, unkind relatives, or unsatisfactory relations with teachers or colleagues at school."

No doubt the result of these studies will be a relief not only to many physicians but also to parents, but they emphasize the importance of careful diagnosis.

PUBLIC HEALTH EDUCATION*

A Health Best Seller—Nearly 2 full columns in the *New York Times* (Dec. 18, 1938), appeared under these headlines:

Little Book on "Infant Care" Is Government's "Best Seller." Starting out in 1914, Its Various Editions Have Had a Circulation of 11,000,000 and It Has Gone All Over the World.

The article announced a revised edition of a little paper-bound book which "has made its mark in the world because of its distinguished rating among the best volumes on this subject" of infant care.

The author writes interestingly about "Infant Care" and "Pre-natal Care," second best seller, how both pamphlets were written, and how they have been distributed and used. Single copies have been loaned widely, and numerous typewritten copies have been made when it was not understood that the government sold them for only 10 cents each.

They Who Know Want to Know More—That the knowingest people are eager learners was brought out in *The Reporter*, 407 7th Ave., New York, N. Y., Sept., 1939. One of the keenest writers on commercial advertising says there:

Direct mail advertising conventions have been going on for 20 years, and every one that I have ever attended turned out to be an opportunity to learn a lot, no matter how much you knew already.

Maybe it's a fact that people who already know a lot about anything are always eager to learn more. Or maybe it is because

you have to know something in order to know how little you know. I've heard both reasons given.

Possibly a Wrong Approach—Famed "Typhoid Mary," in dying not long ago, rendered service to health education. Her death was seized by alert editorial writers to point a health moral. (We wonder how many alert health educators seized the opportunity by submitting the facts to their local or state editorial writers.) *Baltimore Health News* (Jan., 1939) did a good follow-up. Under "Wrong Career" the *News* reprinted the masthead of the *Baltimore Sun* and its editorial on Mary. The *Sun* made an interesting point which may have further application.

Here is part of the editorial:

Perhaps if Mary Mallon had been approached in the right manner, her pride as a cook could have been directed into a legitimate pride as a typhoid carrier. After all, she was the first recognized carrier of the disease, and she provided the medical profession with a useful living model for the study of typhoid distribution and the means to check it. She might have become more coöperative if it had been made plain to her that she was no common carrier of typhoid, but a very distinguished one.

FOR EDUCATION AND STUDY

The first item below tells of something to pass on to the League of Women Voters—that is, after the staff has read it. The second item is for any group concerned with baby welfare.

If any one doubts the utility of sending letters to legislators, he should read "Write Your Congressman Immediately!" by Dwight Anderson, long connected with the National Tubercu-

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evert G. Routzahn, 130 East 22d St., New York, N. Y.

losis Association. Mr. Anderson reports on replies to questions sent to senators, representatives, and New York State legislators. Reprinted from *Public Opinion Quarterly*. Ask Medical Society of State of New York, 2 E. 103rd St., New York, N. Y. *Free*.

"Baby's Daily Time Cards" is a group of 7 cards, 5 by 8 inches, hole at the top, with a knotted cord and the suggestion: "Hang this where you can see it every day." One side of card carries a time table, the other, "Training the Baby," with a card for first 4 months, 5th and 6th months, and so on. At foot of each card is reference to a Children's Bureau publication for further information. Single sets *free* from Children's Bureau, Washington, D. C.

A pay envelope series of folders which ought to get read is put out by Tuberculosis and Health Society, 911 Locust St., St. Louis, Mo. Every month, 30,000 copies of a new folder are distributed through industrial and mercantile establishments (sent only upon request to firms willing to distribute them) and to the Society's library racks in branch libraries, hospital dispensaries, etc. The folders are $2\frac{3}{4}$ by 5 inches, 4 pages on stiff paper (so much better than the flimsy paper sometimes used), limited text and pictures, with modernistic cover which has attention value on a small scale job. The titles:

Don't Take a Chance . . . It Starts by Contact . . . When the Stoplight Signals . . . A Century of Progress . . . and so on.

"Early is the Watchword in Cancer Control" (1 page leaflet); "On the Cancer Front with the Field Army" (folder). Both illustrated. American Society for Control of Cancer, 1250 Sixth Ave., New York, N. Y.

If you wish to look into the possibility that colors may be useful in public health work, see "Color—Our New Star Salesman," by McQueeney and

Podolsky. *Rotarian*, 35 E. Wacker Dr., Chicago, Ill. Jan., 1939. 25 cents. Leads as to color values in printed matter, offices, clinics, equipment, etc., and a reading list.

"Diets of Families of Employed Wage Earners and Clerical Workers in Cities," by H. R. Stiebeling and E. F. Phipard, Bureau of Home Economics, Dept. of Agriculture, Supt. of Documents, Washington, D. C. 140 pp. 15 cents. "What typical American city families are eating and how their diets measure up against nutrition standards." Worth bringing to attention of various groups.

"Social Hygiene: Free and Inexpensive Materials." *American Journal of Nursing*, 50 West 50th St., New York, N. Y. Feb., 1939. 35 cents.

Public Health Nursing, 50 West 50th St., New York, N. Y. (reprints):

The Serum Treatment of Pneumonia, by Rogers and MacChesney (25 cents) . . . Cerebral Palsy, by W. M. Phelps (20 cents) . . . "What's Done We Partly May Compute" (retirement age, etc., etc.) by M. Reid (20 cents).

American Social Hygiene Assn., 50 West 50th St., New York, N. Y.

The Private Physician's Role in the New York City Syphilis Control Activities, by Clarke and Rosenthal . . . This Unofficial Grand Jury (prostitution finding and steps to take) by B. Johnson (10 cents) . . . Gonorrhea—Step-child of Medicine, by E. L. Keyes (10 cents) . . . Catholic Attitude Toward Some Hygienic Legislation, by F. P. Cavanaugh . . . Advice from a Lawmaker (drafting legislation, arousing public opinion, leadership) by T. C. Desmond (10 cents).

FROM THE HOUSE ORGANS

Vigorous editorials or "letters to the editor" on public health topics and quoted from 4 newspapers in *Bulletin*, Dept. of Health, Lincoln, Neb.

The Jenner inquiry has brought to us a life sketch of Eduardo Jenner, "Heroe de la Medicina Preventiva," in *Saludy Sanidad*, Secretaria de Sanidad y Beneficencia, Havana, Cuba.

Probably most of our active educators already are on the mailing lists of *Briefs*, Maternity Center Assn., 1 E. 57th St., New York, N. Y. It brings a wealth of material "for those interested in promoting better maternity care in the United States."

The Bulletin, issued by the 3 national nursing bodies, 50 West 50th St., New York, N. Y., seeks to facilitate being passed around the office. A routing blank is printed in the upper right hand corner of the first page. Under "Pass On To:" are 5 blank spaces for initials or names.

"The Problem of Marihuana" is reprinted by *Connecticut Health Bulletin*, Hartford (Nov., 1938), from *Connecticut Policemen's Journal* for which the article was written by Dr. Millard Knowlton, of the State Department staff. The same issue includes "Planning Ahead for Connecticut's Health," a broadcast explaining the local health department.

Some simple methods for "Teaching People to Drink Milk" are mentioned by J. V. Latimer in *Commonwealth Massachusetts Department of Public Health*, Boston. Oct.-Dec., 1938.

"25 Searching Questions" about local health education activities are asked in *Bulletin*, National Tuberculosis Assn. (Feb., 1939). Although directed to the tuberculosis groups, in connection with the Early Diagnosis Campaign, they largely have pertinence as to the health education activities of other groups. See a copy at the local tuberculosis society office. We wish that some one would write a series of "searching questions" for the local health department to use.

REPORTS

"Po-sho-a-neen - azhe-be-ma - de - ze - yun" ("Hello! How is your health today?") and a picture of an Indian Princess, Watassa, appear on the cover page of Michigan Tuberculosis Assn.

annual report for 1938. Several good 2 page spreads of pictures and captions make the report unusually graphic. The 2 pages on health education are well done.

"Guarding the Health of Kern County," annual report of Kern Co. Dept. of Public Health, Bakersfield, Calif., adds two significant words to the formal note of presentation: "To the Citizens and the Honorable Board of Supervisors." As is so usual, important material is placed in the back where it is likely to be missed by many readers. "Future Goals" and acknowledgments for services rendered seem to deserve a place up front.

The department in a city under 50,000 population might well look over the mimeographed annual report of Middletown, N. Y. To transplant the idea would mean mimeographing 12 sheets on a pleasing ivory paper, with plenty of paragraphs, abundant space between paragraphs. Bits of illustration can be copied from various sources, the copying being done by the girl who is good enough to make properly the typewritten stencil. The health officer or his secretary may not be inclined to lighten the report as freely as is done in Middletown, but with the right paper, spacing, and good stencil making, he will have a report that many citizens will read with pleasure. The 1938 Middletown report does not mention the local population, which the non-resident reader might like to know.

"An Appraisal of East Orange's Health Work" claims *the first page after the cover* of the East Orange, N. J., annual report. This page is a group of horizontal bars with solid black to represent the deficiencies in each 100 per cent based on the appraisal form. Next in the report comes a 3 page "Contents," detailed and in good sized type. *After that* comes the formal statement to the Mayor and City Council, followed by

the Health Officer's 3 page introduction. Popular health instruction is given 2 pages. Next to the last heading is given "Recommendations," which seems a mistake. It may not be logical (to some minds), but surely there would be a far greater reading of the "Recommendations" if they were placed immediately after the introductory pages.

One paragraph from "Foreword" of the "winter issue" of *Delaware Health News* (Dover, Del.), and the chapter headings are quoted below:

As time passes, new public health methods are developed, new needs arise, old health enemies are conquered and new ones challenged. Each of these changes represents a new problem. To lay these problems, clearly and concisely, before the people of Delaware is the purpose of this, the winter issue, of the *Delaware Health News*.

Expenditures and Health . . . We Challenge New Opponents! . . . Assume Responsibility! . . . Santa Claus in a New Rôle . . . Give TB the Knockout Blow! . . . Lifting One Hundred Pounds . . . The Laboratory Is Crowded . . . The Needs of the Health of Delaware.

"A Sight Saving Odyssey." How is that for the title of an annual report? Thus is introduced the 1937-1938 record of Illinois Society for Prevention of Blindness, 203 N. Wabash Ave., Chicago, Ill. There are 28 pages, 5½ by 7 inches, on ivory rough finished paper, blue cover, with the officers on the page after the title and the financial report on the last page, and not a heading between. But it survives that handicap more easily than most reports. This is due to the small size of the pages, the wide margins, the size and readability of the type, the leading between lines, and the lively, narrative style, all in the first person, being report by the Secretary, Audrey M. Hayden. It is no formal "Report of the Executive Secretary." The title origin:

. . . I want to describe to you, if I can, a Sight Saving Odyssey—an Odyssey that

covered 67,786 miles this past year—an Odyssey that carried the message of light to 622 towns scattered through all of the 102 counties of Illinois.

MOVIES AND SLIDES

"Preparing Sound Film Strips," by C. R. Thomas. *Educational Screen*. 64 E. Lake St., Chicago, Ill. Oct., 1938. 25 cents.

Full details described and illustrated, of steps in production of effective teaching material in the form of sound-film-strips.

"We Filmed an Idea" might stimulate workable ideas in presenting health; "How Long Is a Scene?" should help to guard against over-long and too short shots in amateur movies; "Undressing the Act" points to taking the clutter out of indoor scenes; "They Missed Ten Best" explains why certain good movies of 1938 failed to win a place in the annual awards (quite practical); "The Clinic" describes and illustrates short cuts and home-made devices. *Movie Makers*, 420 Lexington Ave., New York, N. Y. Jan., 1939. 25 cents.

"Survey on the Utilization of Visual Aids" is based on returns from about 700 schools. Devoted largely to motion pictures, with limited attention film strips, slides, stereographs, etc. Gives a concise view of current practice. It is interesting that 31 per cent of the schools reporting use 16 mm. cameras "for producing films of school activities for exhibit to parents and community groups." Many teachers reported making movie records of special classroom projects. (We wonder if local health people have been coöperating in either direction to secure health pictures.) Victor Animatograph Corp., Davenport, Ia. Free.

"A School Club's Film," by H. R. Clifford in Feb., 1939, *Movie Makers*, 420 Lexington Ave., New York, N. Y. (25 cents), tells how a junior school group learned to produce their own pictures. A project ahead:

We are working in conjunction with the Safety Commission, another special interest class, on a safety film. We can get plenty of generalized safety films from automobile clubs, the police, etc., but we think it will be worth while to make one of our own that will show the hazards of the blind corners in our neighborhood and that will emphasize the particular habits of our boys and girls which need correction. Furthermore, we think that, even if the film is not outstanding (of course, we are going to do our best), the very fact that sixty boys and girls in the school are thinking, planning and working on a safety problem for several months should make the entire school more safety conscious and more careful.

RADIO

The Health League of Canada (105 Bond St., Toronto) has provided a series of 30 talks which are being broadcast locally over 33 stations in 9 provinces.

"The Hospital Breaks Out of Its Walls," by Dr. H. E. Kleinschmidt, is an effective example of the radio talk, and the title of a radio talk. Tells of the extension of hospital services. In *Hospitals*, 18 E. Division St., Chicago, Ill. Nov., 1938. 50 cents.

MAGAZINE ARTICLES

Magazine articles don't take the place of educational material issued by health agencies, but they do have a lot of supplemental values. Are we getting full value from the magazine circulation in our state or city?

"City Doctor," by J. H. Jerger, M.D. *American Magazine*, Springfield, Ohio, Feb., 1939. 25 cents. "Dictators in Our Hospitals," the case for the general practitioner in city as well as country.

"Let's Wipe Out T.B." Editorial. *Collier's*. Oct. 29, 1938.

"Death to the Killer," by J. D. Ratcliff. *Collier's*. Dec. 24, 1938. "A chemical agent has come to the aid of medicine in its battle against . . . pneumonia."

"Bedtime Story," by H. Lees.

Collier's. Jan. 14, 1939. "Scientists have proved that a good rest doesn't necessarily mean unbroken sleep."

"The War on Syphilis." Editorial. *Collier's*. Feb. 4, 1939.

"*Collier's* two years ago (issue of Feb. 6, 1937) became the first popular magazine to utter the word 'syphilis' in cold type, and to talk about this national health termite and its possible extermination in calm, realistic language."

"The Strange Ways of Allergy," by G. W. Gray. How strange they are, their nature; . . . is there a way out? The writer has been highly praised for lucidity, and a passion for accuracy. *Harper's*, 49 E. 33rd St., New York, N. Y. Jan., 1939. 40 cents.

Under "The Five Sisters" is a bar diagram "record of comparative mental ability at different months." Even without the rather inconspicuous color the diagram is an effective example of how standard diagrams may be dressed up. "Dentistry" is 10 pages of pictures and text illustrative of the makings of an effective exhibit. *Life*, 330 E. 22nd St., Chicago, Ill. Jan. 16, 1939. 10 cents.

"Sleep Pills . . . Friends or Enemies?" "Did you know . . . that these popular, non-habit-forming pills . . . may be poison to you?" *Look*, Des Moines, Ia. Oct. 11, 1938. 10 cents.

Seven pages of pictures showing the how and what of automobile accidents; one page. "Of these 8 Babies, 5 will be killed or injured before they are 60." *Look*, Des Moines, Ia. Dec. 6, 1938. 10 cents.

"The Doctors' 'Union.'" The current case of A.M.A. vs. Dept. of Justice is not "union vs. non-union." It is the Sherman Act and personal conduct. *New Republic*, 40 East 49th St., New York, N. Y. Sept. 7, 1938. 15 cents.

"What Aspirin Does to You," by T. S. Harding; "Inoculation for Your Child" (with "Children's Inoculation

Chart"), by G. E. Pendray; "The Only Fattening Food" ("is too much of all foods"), by J. A. Tobey (Sensible "Reducing"). *Your Life*, 354 4th Ave., New York, N. Y. Nov., 1938. 25 cents.

USING THE MAIL

The 4 page letterhead has its place in the educational as well as administrative correspondence of health agencies. The latest we have noted is for a money-raising letter issued by American Social Hygiene Assn., 50 W. 50th St., New York, N. Y. Letter on first page; committee names and officers on second page: "an 8 point program" stated in detail on third page; fourth page left blank. This form seems better in some cases than an extra, different sized enclosure. Probably the association will send a copy on request. For many uses the two inside pages could be lightened by the use of well laid out pictures, the text being limited as much as possible.

A simple way to give a bit of distinction to our mail is to use the special commemorative postage stamps as they appear. When not available locally they can be secured through the official Philatelic Agency, Washington, D. C. At all times a certain variety of back special issues are offered by the Philatelic Agency. Send postal card for a list when you wish to purchase. Feb. 18, 1939, a "Golden Gate International Exposition Commemorative Stamp" will be put on sale in San Francisco, and may soon be offered in other cities.

Imprinted on envelopes by the postage meter of Baltimore Dept. of Health:

YOUR TAX DOLLAR
GIVES
SECURITY
HEALTH PROTECTION
EDUCATION
RECREATION

SCHOOLS

"Dental Health Education," pre-school and beyond, is presented in *Iowa Public Health Bulletin*, State Dept. of Health, Des Moines, Ia. Oct.-Dec., 1938.

"Dental Hygiene: A Guide to the Dental Hygiene Program in the Schools of New York State" is fourth in a "Health Education Series." University of State of New York, Albany, N. Y.

Essays by about 100,000 students were entered in the 1938 contest conducted by the Committee on Tuberculosis among Negroes. The winners are reported in the Jan., 1939, issue of *Bulletin*, National Tuberculosis Assn., 50 W. 50th St., New York, N. Y.

"Evaluation of a Rural School Health Education Project: A Study of Pupil Health Practices," by Grout and Pickup, is particularly helpful for its analysis of the problem, and the statements running through the report as to the limitations of the methods employed. *Milbank Memorial Fund Quarterly*, 40 Wall St., New York, N. Y. Oct., 1938. 25 cents.

"Health Education" is one of the usual headings over reviews and notes in *Public Health Reviews*, Division of Hygiene and Public Health, University of Michigan, Ann Arbor.

"Health Education in the Michigan Curriculum Program," by G. R. Koopman, presents attitudes and understandings and "nature of an effective program." *Michigan Public Health*, Lansing. Nov., 1938.

The school journey, tour, or excursion has long been a recognized educational device. Have health agencies sought for opportunities to cooperate? "School Tours" is a preliminary report on what schools are doing in trips more than one day in time length. *Free* from U. S. Office of Education, Washington, D. C. Reports are invited from schools, as well as suggestions for making better use of the tour idea.

BOOKS AND REPORTS

The History of Bacteriology—
By William Bulloch, M.D. New York:
Oxford University Press, 1938. 422
pp. Price, \$3.75.

Dr. Bulloch has rendered a service to bacteriologists and to the medical profession in general in giving us this history. In 1930 he wrote the chapter on the History of Bacteriology in that monumental work, *System of Bacteriology*, published by the Medical Research Council of England. In 1937 he gave the Heath Clark Lectures, in which he discussed the development of bacteriology, covering much of the same ground as in his history, but adding greatly to its volume. This book is the result.

The author comments on the curious fact that so little has been written on the history of bacteriology. The only book he knows of in which an attempt to study the development of the history of the science was written by Loeffler in 1887, only the first part of which was published. Since Loeffler has been dead some 25 years there seems to be no hope that the second volume will ever appear.

From the small beginnings in 1675, when van Leeuwenhoek saw minute living creatures in rain water, down to the present, a new science has developed which has reached astonishing dimensions. The author has traced the building up of this knowledge, "often by laborious efforts, by tortuous routes, and sometimes through trackless wastes. But one thing is certain: the science of bacteriology is built on broad and sound foundations."

One is reminded again and again in reading this book of the fact that "... it is a sign of a dry age when the great men of the past are held in light esteem" (Osler). With no desire to belittle the work of modern scientists it must be pointed out that the men of whom this book tells were pioneers without what we now consider even moderate laboratory equipment, and often had to combat prejudices sometimes due to religious, ethnological, or other experiences. There were then no honors such as the Nobel Prize, for example, to be awarded. There was no incentive except a love for the scientific truth to urge them on. As a typical example of this, take the work of Bretonneau (1778-1862). While he is remembered by those who remember him at all as the first man to make a careful study of diphtheria (his essay on this subject is a classic than which nothing better has ever been written), he deserves perhaps more credit for being the real founder of the doctrine of specificity of disease as we understand it today. His conclusions came in the face of powerful tenets to the contrary, especially that of Broussais, who through the important position he held at the Val-de-Grace school exerted enormous influence on the medical thought of the time.

The book is logically arranged in chronologic sequence and shows evidence of an enormous amount of research work. That it is marked by accuracy goes without saying.

A well selected bibliography arranged according to the chapters of the book

occupies 65 pages. There are also some 56 pages given to short biographical sketches of early workers in bacteriology. This includes such men as Appert, for example, who did his remarkable work before there was such a thing as a science of bacteriology.

The book is well illustrated and especially valuable in giving excellent illustrations of some of the early apparatus used in the study of bacteriology. We wish this work could be made a part of required reading for all students of bacteriology. The printing and make-up are of the best.

MAZÝCK P. RAVENEL

Housing Yearbook 1938—Edited by Coleman Woodbury. Chicago: Public Administration Service (1313 E. 60 St.) 1938. 315 pp. Price, \$3.00.

This fourth annual "Yearbook of 1938" outlines in a series of papers and reports some of the highlights of the advance of housing along all fronts during the year 1937. Leaders in five Federal Housing Agencies discuss in individual papers the progress made in their respective fields.

Some 78 pages are devoted to a rather complete summary of housing progress made by states and cities.

A "project roll call" lists large-scale rental housing projects giving their location, name, number of living units, owner, supervisory agency, and financial objective. There are other articles on neighborhood rehabilitation, national appraisal forum, foreclosure-procedures and policy, housing in the Third Reich, British housing in 1937, housing management, homestead tax exemption, Greenbelt Towns, architects in housing, and housing in Canada—all of these by leaders in their particular fields.

Coleman Woodbury, Director of the National Association of Housing Officials, and Editor of this book, sums up a busy year in housing progress

along all of the various fronts and outlines the accomplishments and plans for the National Association of Housing Officials. A personnel of committees; a directory of housing agencies of the nation, state and municipalities; a list of new worth while publications, and, a selected bibliography are given in the last 50 pages of the book.

The reviewer was particularly impressed with a paper by Will W. Alexander, Administrator, Farm Security Administration, who wrote on, "Housing Activities of the Farm Security Administration." He states:

The principal job of the Farm Security Administration is to help farm families on or near relief to become self-supporting. Since 1935 it has helped more than 532,000 low-income families to struggle back toward self-reliance and in helping such people reestablish themselves, the Farm Security Administration inevitably was drawn into the field of housing. By January 1, 1938, the Farm Security Administration had completed about 3,370 homes on resettlement projects, and had nearly 7,000 more under construction. The mean value of all farm dwellings in the United States is only \$1,126 and the median farm tenant home is worth only \$472. It is clear, therefore, that families in need of Farm Security Administration can afford only the simplest kind of housing, compatible with minimum standards of sanitation and comfort. When the Resettlement Administration was incorporated in the Department of Agriculture on January 1, 1937, it was determined that the cost of farm homes should be held below specific levels, ranging from \$1,200 to \$2,100 in different sections of the country. In general, these homes are now being built for as little as \$250 a room without bath and \$300 a room with bath.

It seems to the reviewer that if the aims and motives contained in these statements by the Farm Security Administration were made the aim and motive force back of our federally directed urban housing movement, public health authorities would certainly become intensely interested overnight in housing.

In the first article in the yearbook the first purpose of the United States

Housing Act as outlined by Katherine K. Bauer, is given as follows:

To provide financial assistance to the states and political subdivisions thereof for the elimination of unsafe and insanitary housing conditions, for the eradication of slums, for the provision of decent, safe, and sanitary dwellings for families of low income, and for the reduction of unemployment and the stimulation of business activity . . .

It would seem that the last twelve words of this statement of purpose should be an incidental result rather than a driving purpose of any fundamentally sound program to provide minimum standard housing for the poor.

This book is full of thought provoking articles for health officials having any interest in the housing movement of today.

ALFRED H. FLETCHER

The Adolescent—By *Ada Hart Arlitt, Ph.D.* New York: McGraw-Hill, 1938. 242 pp. Price, \$2.00.

Adolescence, between 12 and 21 years of age, is probably the most difficult time in an individual's life, most trying, not only for himself but for the adults who are to guide him. He does not understand his own feelings, his own rapidly maturing body, his constant struggle to make himself felt as an individual. Frequently he is a member of a family in which the parents do not wish their children to grow up to become individuals independent of them; and so, to himself and to his parents, to his teachers and to other adults who come in contact with him he is a very puzzling individual, and all too frequently is called a problem.

Dr. Arlitt's book is one which could be read with profit by all adults. She gives practical advice on ways of meeting the problems of this age in language which makes delightful reading and which shows a rare and sympathetic understanding of adolescence.

ETHEL GORDON

A Manual of Tuberculosis: For Nurses and Public Health Workers—By *Ashworth Underwood.* Baltimore, Md.: Wood, 1938. 404 pp. Price, \$3.25.

In the light of modern developments in tuberculosis control, the increase in the practice of chest surgery, and the more recent conceptions of the method of tuberculous infection in the child, the author has completely revised the earlier edition of this volume which was published in 1931. Three new chapters have been added describing briefly administrative phases of tuberculosis work.

With an orderly presentation of material the book has 18 chapters, the first two of which describe in plain language the general nature of tuberculosis; then come chapters on symptoms, signs, and the course and complications of pulmonary tuberculosis. Following are discussions of sanatorium and medical treatment of the disease with special reference to collapse therapy, operative methods, and diagnosis of treatment. Individual chapters are devoted to tuberculosis in children, and tuberculosis of bones and joints. The use of tuberculin and laboratory methods of diagnosis are given a full chapter. There is a detailed description of nursing duties in sanatorium treatment and on the private nursing of tuberculosis. Other chapters are devoted to light therapy, disinfection, the duties of the nurse in the dispensary, and the post-sanatorium regime including instructions to the patient.

The book was written primarily to prepare the nurse for work in the special field of tuberculosis, but its horizons are even more extensive. The descriptions are unusually clear, the language is simple. Fifty-three illustrations accompany the text. A useful glossary of technical terms and a bibliography for further study are provided. The sum-

maries at the end of the chapters form a syllabus on tuberculosis for nurses and public health workers who will find the volume an excellent source of information. BERNARD S. COLEMAN

Tuberculosis Hospital and Sanatorium Directory, 1938—*New York: National Tuberculosis Association, 1938. 168 pp. Price, \$1.00.*

The National Tuberculosis Association has issued, as of May, 1938, an up-to-date Directory of Tuberculosis Hospitals and Sanatoria in the United States, including institutions in Alaska, Hawaii, Puerto Rico, and the Philippine Islands. Listed alphabetically according to location under the separate states and territories the names of the institutions, 749 in number, are followed by their dates of opening, the types of cases accepted, bed capacities, rates, qualifications of residence of patients admitted, the names of the superintendents and the medical directors, and the persons to whom application for admission should be made. A separate listing is given for Federal Sanatoria and Hospitals which provide facilities for the care of the tuberculous.

The Directory reveals the astonishing development that has occurred in tuberculosis hospital care in the United States since Dr. Edward Livingston Trudeau opened the "Little Red," the cottage of two beds in Saranac Lake in 1885. The erection of sanatoria in state after state following Trudeau's demonstration has been a constant and progressive development until there are now available in continental United States 732 institutions with close to 90,000 beds. Alaska, Hawaii, Puerto Rico, and the Philippine Islands have 17 institutions with approximately 3,100 beds. If and when the hospitals now under construction or definitely provided for are completed there "should be available within the next few years approximately 98,000 beds."

This edition of the Directory shows an increase of 5,869 beds since 1934 when the previous edition was published.

The Directory is useful to tuberculosis specialists, tuberculosis and health associations, departments of health, hospitals, and public welfare, and should be on the desk, for ready reference, of every health and hospital information service in the country. It provides "quick" information. The volume is well printed and has been indexed thoroughly. BERNARD S. COLEMAN

Annual Report of the Surgeon General of the Public Health Service of the United States for the Fiscal Year 1938. *Washington: U.S. Government Printing Office, 1938. 184 pp. Price, \$.60.*

This small volume contains a wealth of information of great interest. Not only does it tell of health conditions in this country but there is also a brief report concerning those in the world in general. Unfortunately such reports are at least 6 months old and sometimes more before they are published.

In the world there were 198,389 cases of cholera reported for 1937, with 101,201 deaths, of which 86 per cent occurred in India. Only 1 case with death was reported in the Philippine Islands. There were 36,000 cases of plague with 22,000 deaths, an increase over 1936. There were reported 137,856 cases of smallpox with 28,000 deaths, a great proportion of which—104,974 cases with 26,447 deaths—occurred in India. Unfortunately, "the United States continues to hold its unenviable position near the top among the nations reporting smallpox incidence. For 1937, 48 states reported a total of 11,673 cases of smallpox, as compared with 7,834 for 1936 and with 7,957 for 1935. The number of cases for 1937 is the highest since 1931, while the number of deaths (30) compares favorably with the average of 26 per

year for the preceding 3 years." Of yellow fever there were 314 cases with 290 deaths, 13 cases of which, with 8 deaths, were the jungle type reported from Peru. The disease was practically confined to Africa and South America. All continents reported the prevalence of typhus fever, with a total of 30,326 cases with 1,753 deaths, an increase over 1936.

For the United States general conditions were favorable. In spite of a small epidemic of influenza during the first quarter of the year, the general death rate for 40 states, District of Columbia, and Hawaii, representing 85 per cent of the total population of the country, was 10.9 per 1,000 as compared with 11.3 for 1936. These figures are preliminary and the final corrected rates by the Bureau of the Census will differ somewhat. However, the provisional rates of the Census indicate a decrease of 3 per cent in 1937 over 1936. These favorable health conditions continued into 1938 and the rate for the first half of 1938 was 10.8 per 1,000, as compared with 11.8 for the corresponding period of 1937. The infant mortality rate showed a decline of more than 8 per cent and maternal mortality also showed an encouraging decrease—from 5.3 for 1936 to 4.6. The tuberculosis mortality rose in 1936, but in 1937 the downward trend was re-established, standing at 49.6 for all forms against 51.7 for 1936.

Studies in Rocky Mountain fever have continued and the known area in which it is found has been extended to include all geographic regions of the United States, New England being the last to recognize its occurrence, with 4 cases reported in Rhode Island in 1937. In all, there were 431 cases and 86 deaths for 1937.

New low death rates were recorded during 1937 for typhoid fever, scarlet fever, diphtheria, tuberculosis, malaria, pellagra, nephritis, and diseases as-

sociated with pregnancy and childbirth.

The leading causes of death for 1937, according to preliminary data, were diseases of the heart, cancer and other malignant tumors, pneumonia (all forms), cerebral hemorrhage and softening, nephritis, accidents (except automobile), and tuberculosis, in the order named.

The personnel of the Service as of July 1, 1938, consisted of a total of 481 officers, of whom 60 were on waiting orders. On the same date the number of reserve officers on active duty was 91. There were also on that date 726 Acting Assistant Surgeons.

The report contains interesting sections telling of the researches being done in the Division of Domestic Quarantine (States Relations), being the public health program under title VI of the Social Security Act.

The whole report is full of meat, but is in such detail that it does not lend itself readily to review. It must be read to be appreciated.

The United States is fortunate in having in the Public Health Service one of the largest, best equipped, and best trained forces of men in public health work that the world affords.

MAZŮCK P. RAVENEL

Foods: Production, Marketing, Consumption—By Jean J. Stewart. New York: Prentice-Hall, 1938. 737 pp. Price, \$3.25.

From crop production to table etiquette here is a book replete with information about foods and of real value to the health officer, nurse, physician, dietician, and food technologist. As much at home in the classroom as in the reference library of a research laboratory, this comprehensive volume will stimulate the layman to think more about foods and at the same time awaken an interest in the expert. The text is well written and easy to read, supplemented, as it is, by illustrations,

charts, and tables. The author has successfully attempted to discuss man's food problems from production and marketing to consumption and human nutrition. No small value lies in the up-to-date bibliography at the end of each chapter.

A description of the individual food-stuffs is presented including a survey of the industry, chemical and bacterial significance, and nutritive values. Classification and government grades and standards are given in most cases. For those foods which are manufactured, a description of the processing steps and the theory behind each is developed including some discussion of the factors affecting quality. In one book covering such a broad subject too much exhaustive discussion cannot be expected. All topics are treated in a concise style but with surprisingly little sacrifice of detail except in very technical matters.

High carbohydrate foods, fruits and vegetables, fats and oils, meats and fish, poultry and eggs, and beverages are discussed in separate chapters. Other chapters include a study of man's relation to the food problem and the food needs of the individual, the family, and the nation. The latter deals with the factors and agencies concerned in promoting a national program of optional nutrition and with cleanliness and sanitation.

The author has taken a modern attitude in coördinating the interests of producers and consumers. However, the educational value of this book does not stop here. The public health worker will find it very informative not only in its text material but also in the appended charts of food consumption statistics and dietary values. In addition, there is a section on meal planning, cooking, and even table service; the food buying guides and shipping season charts are quite useful. Definitions for milk grades and standards for

milk production as defined in the U. S. Public Health Service Ordinance are included, also a personal health data chart including height-weight-age tables compiled by qualified investigators.

A better understanding of the complex interrelationships involved in the social and economic aspects of food is desirable, and through education such as this books offers, life can be made more interesting and more efficient.

C. R. FELLERS

Gould's Pocket Pronouncing Medical Dictionary—By *George M. Gould, M.D.* Revised by *C. V. Brownlow (11th ed.)*. Philadelphia: Blakiston, 1939. 1,056 pp., 218 pp. of tables. Flexible washable fabric binding. Price, \$2.00; Thumb index, \$2.50.

The eleventh edition of this standard work is in a handy size for the use of those for whom the full-size volume is unwieldy.

On the whole it would seem that the abbreviation involved in this small-size dictionary does not seriously reduce its usefulness to physicians, public health workers, medical writers, nurses and many others who need a readily accessible source of information for our rapidly increasing scientific vocabulary.

Having moved the tables to the Appendix, the main body of the volume of more than a thousand pages is left free for the definition of a surprising variety of terms. Any volume in this field which sells close to 900,000 copies has evidence of its utility.

REGINALD M. ATWATER

A Guide to Human Parasitology for Medical Practitioners—By *D. B. Blacklock, M.D., and T. Southwell, D.Sc.* (3rd ed.). Baltimore: Wood, 1938. 259 pp. Price, \$4.00.

The authors are members of the faculty of the Liverpool School of Tropical Medicine. In this third edition most of the book remains the same

as before except for the inclusion of the most recent advances in knowledge. The chapter on malaria has been entirely rearranged in order to facilitate the study of the subject, and the section on Leishmaniasis has been largely rewritten in the light of the most recent investigations.

The book is a brief textbook for students of human parasitology and for practitioners in the tropics. It is on the whole very accurate with regard to the morphological characteristics and life cycles of parasites. The two colored plates and 122 illustrations in the text, most of which appear to be original drawings, are excellent.

An attractive feature which is rarely found in textbooks of parasitology is a series of charts showing the life cycles of most of the helminths. This is included in a section on diagnosis, which is inserted in the chapter on nematodes without being mentioned in the table of contents.

The value of the book is limited by the omission of important points connected with a number of parasites, such as the globulin tests in the diagnosis of kala azar. Clinical symptoms, treatment and prevention are entirely omitted throughout the book. The reviewer believes that the book would receive much wider approval, especially as a textbook for medical students, if these features were added.

HENRY E. MELENEY

Your Chest Should Be Flat—
By S. A. Weisman. Philadelphia: Lippincott, 1938. 145 pp. Price, \$2.00.

This exceedingly well conceived and orderly little book contains the report of a study of the thoracic measurements of 20,000 school children. The conclusion that the deep chested child is slightly more prone to tuberculous infection than the flat chested individual appears to be well substantiated. It

still leaves us somewhat in doubt as to an adequate reason for this observation. The brief chapter on preventive measures is definitely suggestive. In this are recognized the handicaps imposed by substandard economic conditions. It might be suspected that these were the causes of both barrel chest and lowered resistance to infection by the tubercle bacillus. Even so, the careful research makes its significant contribution and represents a study of definite value.

The form and manner of presentation deserves high praise. If more research could be reported in so attractive a manner, its practical value would be notably increased. Illustrations, chapter summaries, and excellent bibliographies add much to the value of the book. Aside from the interesting conclusions regarding physical configuration and susceptibility, the many wise comments on tuberculous infection in childhood lend essential value to the book. It is strongly recommended to readers, both for its form and its content.

KENDALL EMERSON

Fifth Avenue to Farm: A biological approach to the problem of the survival of our civilization—
By Frank Fritts and Ralph W. Gwinn. New York: Harper, 1938. 282 pp. Price, \$3.00.

This analysis of the problem of the eugenic quality of American civilization suggests that historically the best biological specimens have come from farms and small towns. Implications related to the effects of higher birth rates in the rural than in the urban areas, of the migration from farms to cities, and the responsibilities of American colleges and of churches in relation to problems of a changing society are considered. Students interested in population problems and in the interrelationships of the various factors of modern society will be par-

ticularly interested in this study which is likely to provoke controversy as well as to stimulate thinking regarding future trends. IRA V. HISCOCK

Sanitization of the Drinking Glass: Part One, Methods and Procedures—*By Jack G. Baker; Part Two, Practical Control, By Raymond V. Stone, D.V.M. Los Angeles: National Association of Sanitarians, Inc., 1938. 60 pp. Price, \$.25.*

This concise, comprehensive, handbook will be found a dependable guide by health officers and sanitary inspectors who wish to establish or improve methods which concern the sanitation of public eating and drinking establishments in their communities. The text is entirely practical and is written by individuals of experience who are convinced of the epidemiological significance of the subject which they have studied so systematically and constructively.

In Part One the fundamental demand for clean eating and drinking utensils is presented clearly; however, the difficulty of establishing conclusively exactly where and when infection takes place is definitely realized. It is only in studies made upon large groups under control that data of even approximate accuracy can be obtained.

The responsibility for the adequate sanitation of eating and drinking establishments is put squarely up to the health officer, where it truly belongs, but for a health officer to launch such a "program without giving thought to the industry is a serious mistake." Methods must be devised which are practical as well as effective, which take into consideration the availability of equipment, and which can be adopted and applied with ease and certainty. The fundamental purpose of this publication is to tell the health officer exactly how this is to be accomplished.

A well deserved tribute is given to

individual service paper drinking cups. Their universal adoption would relieve the health officer of one of his most difficult administrative problems.

Probably no section of this work will be found more welcome than that which concerns Inspectional Procedures. Any campaign which has as its aim the sanitation of public eating and drinking establishments must depend, in the main, upon the conscientious work of the sanitary inspector. Even the bacteriological work of the laboratory is very secondary in its ultimate value. Much time has been spent by careful investigators in attempts to find the ideal bacteriological set-up. About all we actually need is a method whose results will indicate the difference between relatively clean and relatively dirty dishes and glasses. There is, however, the need for universal agreement upon a standard technic. There are two reasons for this—among others. The first is that a commonly accepted and applied technic is the only one which will enable health officers to compare the results of their work; the second is that an official standard method carries authority in a court of law. The health officer is already convinced of the value of standard methods; the laboratory man does not want his research hampered even by implication; and the sanitary inspector merely wants to know definitely and clearly what he is to do and how it is to be done. This text permits him to have no further doubt.

Part Two concerns Practical Control. In addition to his thorough discussion of laboratory procedures and the background for such work, Dr. Stone contributes his own observations upon a sediment test for the wash water. For making this test the Wisconsin or the Vacuum Sediment Tester is used. An ounce of the dish water is passed through, and then the disk is removed, pressed upon a small white card, and

dried. It can thus be preserved for any subsequent use, such as exhibition in court.

The tentative procedure suggested by the American Public Health Association Sub-Committee on Standard Methods for the Examination of Dishwashing Devices (published in the 1936-1937 *Year Book*) has been adopted by Dr. Stone. He finds that the temperature of the wash water should not go below 120° F., that the sediment tester makes bacteriological examination of the wash water unnecessary, and that an allowable rim count per drinking glass of 500 colonies is too lenient—he suggests a maximum of 100 colonies.

"An objection that 'standardization impairs progression by discouraging research' is not tenable. Actually research ideas carried concurrently with a standard procedure is the only way to evaluate the degree of superiority (or even inferiority) of the planned innovation. Standard Methods increase the research trend since a measuring rod exists which allows comparisons. Let there be more Standard Methods; more Tentative Methods and fewer Optional Methods."

This work is recommended without qualification to all persons interested in clean public drinking glasses.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Safety Last—As the price we pay for our "glorious fourth" we can mark up 25 deaths (mostly little girls burned by sparklers setting fire to flimsy clothes and big boys killed by home-made explosives) and about 8,000 cases of serious injuries such as the loss of eyes, arms or fingers. New Jersey, with an effective fireworks ban had the lowest score, while across the Delaware River, the Keystone State had the distinction of killing and maiming the most.

ANON. Second Annual Summary of Fourth of July Injuries. J.A.M.A. 112, 3:236 (Jan. 21), 1939.

Dental Defects and Diet—All free sugar was taken from the diet of institutional children, a diet which, incidentally, was inadequate from the standpoint of the protective foods. Despite evidences of malnutrition, from 80 to 90 per cent of the children became free of dental caries. Also the oral acidophilus disappeared. When candy and free sugar was fed, the salivary acidophilus bacillus returned and after a period so did dental caries. Acid-producing bacteria determine the occurrence of caries regardless of all other factors. A diet of starches and sugars only affects these germs. If these findings are accepted by all authorities, health educators are going to have a lot of "un-learning" to do.

BUNTING, R. W. Diet and Dental Caries. New York State J. Med. 39, 1:18 (Jan. 1), 1939.

Sprayed Apples and Cabbages—Hinting darkly of "dirty work at the crossroads" this paper pictures the possibility of unrecognized chronic

poisoning by the lead, arsenic, and fluorine used as fruit and vegetable sprays. Difficulties in nutritional research are presented in considering the need for control.

CARLSON, A. J. Some Complications in Nutrition Research. J. Am. Dietet. A. 15, 1:1 (Jan.), 1939.

Why Filing Cases Multiply—Record keeping is considered so important in public health nursing that visits are not counted unless the case record is completed. To what use are the records put? It is assumed they are of value as an influence for more complete follow-up. In this paper it is concluded that the time spent in making the common type of entry is largely wasted in so far as that benefit is concerned. This is not a general condemnation of record keeping.

DERRYBERRY, M. Do Case Records Guide the Nursing Service. Pub. Health Rep. 54, 3:59 (Jan. 20), 1939.

Health for All—Another, and an excellent statement both of the need for, and the proposals to accomplish, a national health program addressed to staid New England, where there is a much more progressive attitude toward modern health problems than "Plymouth Rock" traditions would lead to one to expect.

DRAPER, W. F. A National Health Program. New Eng. J. Med. 220, 2:44 (Jan. 12), 1939.

Can You Remember What You Read?—These suggestions for student nurses about how to study, concentrate, and remember are worth perusal by any health worker who has difficulty making his mind behave. Six good

rules for mental efficiency end the discussion.

KITSON, H. D. There's Nothing Wrong With Your Mind! *Am. J. Nurs.* 39, 2:117 (Feb.), 1939.

What School Physicians Ought to Know—Herein is discussed the training of school physicians. It is proposed that institutes and teaching centers be created where physicians may learn the elements of school health work, and that educational standards be fixed by State Departments of Public Instruction.

KLEINSCHMIDT, E. E. Special Educational Qualifications for the School Physician. *J. School Health.* 9, 1:13 (Jan.), 1939.

Teaching About Cancer—Beginning a series of articles reviewing the symptomatology and treatment of cancer, this first paper promises a discussion of wider interest than just for the public health nurse to whom it is addressed.

KRESS, L. C. The Nurse's Part in the Control of Cancer. *Pub. Health Nurs.* 31, 2:85 (Feb.), 1939.

Fat Soluble Vitamins—Briefly and skillfully reviewed as in this article, the present-day knowledge of vitamins A and D can be made quite comprehensible to those of us who are not biochemists. The author concludes that an ample and varied diet rich in dairy products will supply all the fat soluble vitamins that the body needs, except during infancy, pregnancy, and lactation; then fish liver oils may be needed.

MEIKLEJOHN, A. P. The Fat Soluble Vitamins. *New Eng. J. Med.* 220, 2:67 (Jan. 12), 1939.

Twenty-five Colleges—Where to go for undergraduate training in sanitary and public health engineering.

MILLER, A. P. Undergraduate Engineering Training in Public Health and Related Activities in Engineering Colleges of the United States. *Pub. Health Rep.* 54, 2:29 (Jan. 13), 1939.

Nurses and Tuberculosis—Tuberculosis constitutes an occupational hazard for public health nurses. Although the number of open cases is decreasing, the nurse is often exposed to the disease. Her only defense is good communicable disease nursing technic. The only way she, or anyone else, can get the disease is from some one of her contacts who has it.

MYERS, J. A. Tuberculosis Among Nurses. *Pub. Health Nurs.* 31, 2:93 (Feb.), 1939.

Creating Good Will—Words of wisdom about the public relations of a municipal water company, every syllable of which would apply equally to any health agency. The paper is commended to all administrators, both for the needed lessons it contains and for the manner of its presentation.

NILES, P. B. Watering the Grass Roots. *J. Am. W. W. Assoc.* 30, 12:1917 (Dec.), 1938.

Preventing Pertussis — Double strength vaccine given subcutaneously in 3 weekly doses appears to confer practical protection. Passive immunity may be achieved by use of hyperimmune serum, if given before the paroxysmal stage is reached. These are two conclusions from an interesting paper reviewing the modern situation in regard to the disease.

SAUER, L. W. Whooping Cough. *J.A.M.A.* 112, 4:305 (Jan. 28), 1939.

ASSOCIATION NEWS

The attention of overseas public health workers is called to the extraordinary opportunity in 1939 of attending the meeting of the American Public Health Association and one or both of the World's Fairs in San Francisco and New York, where special emphasis has been laid on public health exhibits.

Sixty-eighth Annual Meeting, Pittsburgh, Pa., October 17-20, 1939
Headquarters: Hotel William Penn

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Erb. na Bangxang, M.B., C.P.H., 615 No. Wolfe St., Baltimore, Md., Deputy State Health Officer, Bangkok, Siam
Benjamin S. Black, M.D., Grove Hill, Ala., Clarke County Health Officer
Grover C. Bolin, M.D., Riverside Drive, Orangeburg, S. C., Director, Orangeburg County Health Dept.
Randolph L. Compton, M.D., Greenup, Ky., Director, Greenup County Health Dept.
John F. D. Cook, M.D., State Capitol Bldg., Pierre, S. D., Superintendent, State Board of Health and Medical Examiners
Benjamin M. Drake, M.D., Greensboro, Ala., Hale County Health Officer
Lenor S. Goerke, M.D., C.P.H., 324 Duane, Astoria, Ore., Clatsop County Health Officer
Adelard Groulx, M.D., C.P.H., Dept. of Health, City Hall Annex, Montreal, Que., Canada, Director
Reuben J. Harrington, M.D., Court House, Muskegon, Mich., Director, Muskegon County Health Dept.
Andrew Hedmeg, M.D., Box 332, Natchez, Miss., Director, Adams County Health Dept.
Roscoe P. Kandle, M.D., C.P.H., Tenth District Health Office, Clovis, N. M., District Health Officer
John R. Long, M.D., Marion, Ala., Perry County Health Officer

Bennie A. Moxness, M.D., 165 Capitol Ave., Hartford, Conn., Public Health Physician, Bureau of Venereal Diseases, State Dept. of Health
S. Stewart Murray, M.D., D.P.H., City Hall, Vancouver, B. C., Canada, Senior Medical Health Officer, Greater Vancouver Metropolitan Health Committee
J. Burris Perrin, M.B., C.P.H., 422 State Office Bldg., Denver, Colo., Director, Maternal and Child Health, State Health Dept.
John S. Robertson, M.D., D.P.H., P. O. Box 130, Yarmouth, N. S., Canada, Divisional Medical Health Officer
Livingston B. Sheppard, M.D., Box 708, Paintsville, Ky., Johnson County Health Officer
Thomas B. Snoddy, M.D., Pala, Calif., Field Physician, Mission Indian Agency, U. S. Indian Service
Ellis D. Sox, M.D., C.P.H., 1501 W. Main St., Visalia, Calif., Tulare County Health Officer
Joseph H. Stickler, M.D., Stewart, Nev., In charge of Division of Health, Carson Indian Agency, U. S. Indian Service
Ernest Thompson, M.D., Monroe, Ga., Walton County Health Commissioner
Floyd R. Town, M.D., Mt. Pleasant, Mich., Director, Isabella County Health Unit
Ralph M. Vincent, M.D., M.P.H., 65 Broad St., Rochester, N. Y., Assistant District State Health Officer

NATIONAL HEALTH COUNCIL

AT a recent meeting of the Executive Board, the entire question of continued participation by the American Public Health Association in the activities of the National Health Council was considered, and the Executive Board confirmed the selection and appointment of John A. Ferrell, M.D., Louis I. Dublin, Ph.D., and Reginald M. Atwater, M.D., as delegates to the National Health Council, but on a temporary basis. The Board directed its delegation to inform the National Health Council of its desire for a definite statement as to the present activities of the Council in the field of joint planning and as to any proposed program of action which the Council may have in mind for the immediate

future. In making this request the Board indicated that it is not convinced of the desirability of continued membership in the Council.

ASSOCIATION REPRESENTATIVES

CHARLES F. WILINSKY, M.D., Director of Beth Israel Hospital, Boston, has been reappointed liaison officer between the A.P.H.A. and the American Hospital Association.

W. S. LEATHERS, M.D., Dean of Vanderbilt University School of Medicine, Nashville, Tenn., has been appointed as Association representative to the meeting of the Advisory Council on Medical Education, Licensure and Hospitals, held in Chicago, February 12 and 13.

EMPLOYMENT SERVICE

The Employment Service will register persons qualified in the public health field without charge.

Replies to these advertisements, indicating clearly the key number on the envelope, should be addressed to the American Public Health Association, 50 West 50th Street, New York, N. Y.

POSITIONS AVAILABLE

WANTED—(a) Student health physician; state university; some teaching; opportunity graduate training. (b) College nurse; state teachers' college; college degree required; \$125, maintenance; southeast. (c) Public health nurse; some administrative duties;

municipal department of health; middle-west. (d) Public health nurse; to supervise outpatient department, children's hospital; some teaching duties. WRITE: 339, Medical Bureau, Pittsfield Building, Chicago, Ill.

POSITIONS WANTED

HEALTH OFFICERS

(a) Public health physician desires connection; M.D., Virginia; several years' successful private practice; 10 years' public health work during which time he has been promoted continuously; excellent reason for relocating. (b) Health educator; A.B., Wellesley; M.S. in public health from state university; 6 years, teaching physiology and sciences in public schools; 2 years, director of child health education, national organization; 2 years, health counselor and teacher of health education, midwest metropolis; 4 years' social work. For further details, please write

M. Burnice Larson, Director, Medical Bureau, Pittsfield Building, Chicago, Ill.

Unusually well qualified and experienced administrator, M.D., Johns Hopkins, M.P.H., Harvard, with broad experience in administering programs of medical care, is available. A404

Experienced public health executive; 10 years as full-time county health officer; 4 years as state commissioner of health, wishes administrative position of responsibility. A403

Physician, M.D., Syracuse University; post-graduate studies in bacteriology and immunology, will consider position as health officer or epidemiologist. Has served as

EMPLOYMENT SERVICE (Cont.)

POSITIONS WANTED (Cont.)

director of county health unit, director of industrial hygiene and medical statistics and venereal disease field survey officer. A305

Physician, M.D., Class A medical school; M.P.H., Harvard School of Public Health; extensive experience in pediatrics and school medical services; also background of county health administration and teaching in medical school, will consider expanded opportunity in teaching or research. A302

Experienced physician, administrator, epidemiologist, and teacher, now employed, with C.P.H. from Johns Hopkins, and 14 years' public health background, will consider position. Prefers epidemiology in city or state department. Excellent references. A355

Physician, M.D., Columbia, experienced as county health officer and superintendent of health, seeks position in public health administration or medical executive work. A396

Physician, M.D., St. Louis University; now completing M.S.P.H., University of Michigan; 10 years' experience as county and city health officer, seeks full-time public health administrative position. A373

Physician with M.P.H. from Harvard, experienced as epidemiologist and in county health administration, also in communicable diseases at state level, seeks responsible position. A392

Physician, M.D., Class A medical school; M.S.P.H., University of Michigan, 1937; now serving as district state health officer, seeks full-time city or city-county administrative position. A367

Physician, M.D., Vanderbilt University; Dr.P.H., Johns Hopkins; experienced as epidemiologist, health officer and professor of preventive medicine, seeks position as administrator or epidemiologist. A397

Physician, M.D., University of Cincinnati; with postgraduate training in venereal disease control, Johns Hopkins; now employed, is available as venereal disease control officer. A363

HEALTH EDUCATION

Experienced teacher in public health and author; M.A., Columbia; now teaching public health nursing and carrying field promotion, wishes broader opportunity to train field personnel in extending health knowledge and interest to the general public, especially through group education, institutes, exhibits and rural programs. H400

Well qualified woman in health education wishes position as health coördinator or health counselor. Has wide experience, and Ph.D. from New York University. H236

Young woman, experienced teacher in health education, with M.S. in Public Health and Hygiene from University of Michigan, seeks position as health coördinator. H398

LABORATORY

Laboratory technician, B.Sc. degree; with experience in Army, state public health laboratory and U. S. Public Health Service field laboratory, seeks position in medical school or university. L379

Woman bacteriologist; B.A., Chemistry, 1933; 5 years' experience in experimental and practical therapeutics including animal work; desires position in public health field. L394

Bacteriologist and pathologist with wide administrative experience; Ph.D., Brown University, will consider leading position in this field. L371

MISCELLANEOUS

Medical social worker, graduate of Tulane University, with 18 years' hospital experience, is available for position; especially interested in programs of public medical care. B401

Experienced teacher of bacteriology and hygiene; M.D., University of Pennsylvania; excellent connections, wishes to secure teaching position. M402

NEWS FROM THE FIELD

NEW YORK UNIVERSITY INSTRUCTION IN PREVENTIVE MEDICINE

A NEW program for instruction in preventive medicine for medical students has been announced by Dr. Currier McEwan, Dean of New York University School of Medicine, made possible by a grant of \$84,000 from the Commonwealth Fund. The new arrangement will comprise studies covering the entire four year period and will be centered around the Department of Preventive Medicine and the Hermann M. Biggs professorship in preventive medicine. Dr. Harry Stoll Mustard, Director of the Department, will be in charge of the program and it will be conducted by a full-time staff of instructors and technicians. Rather than to concentrate studies in preventive medicine on the last two years of the regular medical college work, it will now begin in the freshman year and will include activities at a teaching and research center provided in the facilities of the lower East Side Health District, the use of which has been made possible through the coöperation of the New York City Department of Health.

NATIONAL SOCIETY FOR PREVENTION OF BLINDNESS

THE National Society for the Prevention of Blindness has announced that Lewis H. Carris, managing director, assumed the title of general director on January 1, with Mrs. Winifred Hathaway as associate director.

Eleanor Brown Merrill, an associate director for the past five years and formerly secretary of the Society, becomes executive director, and will relieve Mr. Carris of administrative details.

John M. Glenn, one of the founders of the National Society for the Prevention of Blindness, has been elected an honorary vice-president.

COLORADO PUBLIC HEALTH ASSOCIATION

OFFICERS of the Colorado Public Health Association for 1939 are announced as follows:

Amos L. Beaghler, M.D., *President*
Roy L. Cleere, M.D., *Vice-President*
Helen Cannon, *Secretary*
Omer R. Gillett, M.D., *Treasurer*

UNIVERSITY OF MINNESOTA FELLOWSHIPS

THE University of Minnesota has announced a limited number of in-service fellowships in Public Administration for the academic year 1939-1940. The period of training will extend from the beginning of the fall term through the first term of the summer session, and individual courses of study will be planned for each student depending upon previous preparation, personal interests and the requirements of public service. These in-service fellowships will carry stipends varying in amount from \$1,000 to \$1,500 a year, depending upon the student's experience, his present salary and the number of his dependents. Credit earned in residence at the University during the training period may be applied toward advanced degrees.

Applications for these fellowships for the academic year 1939-1940 are to be submitted not later than April 1, 1939, to the Secretary of the Committee on Training for Public Administration, 13 University Library, University of Minnesota, Minneapolis. Those applicants employed in such functional departments as health and sanitation should have had at least a minimum of preparation in political science and other social sciences. Each applicant must be endorsed by his governmental employer and should secure promise of a leave of absence for the duration of his fellowship year.

VACCINES FOR CHINA

THE Chronicle of the Health Organization, League of Nations, Geneva, reports that in 1938 the Chinese health authorities, faced with the threat of a cholera epidemic, asked the League to supply them with six million doses of vaccines. With the generous support of 13 countries, including the United States, the Health Organization succeeded in less than 4 weeks in procuring eight million doses free of charge.

In thanking the countries concerned, the Council of the League drew special attention to this striking example of the part which the League of Nations can play in the field of international humanitarian assistance.

NORTH CAROLINA SYMPOSIUM
ON SYPHILIS

IT is announced that a Symposium on Syphilis will be held at Duke University, Durham, N. C., March 24-25. This symposium is being sponsored by the North Carolina State Board of Health and Duke University.

The following speakers have been scheduled: Dr. Thomas Parran, Dr. John H. Stokes, Dr. J. Earl Moore, Dr. H. N. Cole, Dr. Paul O'Leary, Dr. P. C. Jeans, Dr. Norman R. Ingraham, Dr. Carl V. Reynolds, and Dr. William deB. MacNider.

HONOLULU MENTAL HYGIENE CLINIC

A CLINIC for mental hygiene was recently established in Honolulu to serve the Territory of Hawaii. Dr. Franklin G. Ebaugh, of Denver, Colo., supervised the organization.

A unit at Queens Hospital has been given over to the clinic to provide hospitalization and treatment facilities. Dr. Edwin E. McNeil, of New York, was to take charge of the clinic October 18. Steps were recently taken to initiate mobile mental hygiene clinics to serve these islands.

LOS ANGELES HEALTH DEPARTMENT
FILM

THE Los Angeles City Health Department has ventured into a new field, as part of its recent annual report. It has recently completed a motion picture, 45 minutes in length, which shows in detail the functions of its various departments.

The film is divided into three reels, as follows: Reel I, Division of Public Health Education; Library; Division of Laboratories; Epidemiology—Quarantine—District Doctors. Reel II, Women's Venereal Diseases; Men's Venereal Diseases; Tuberculosis Division; Nursing Division; Child Hygiene; Housing and Sanitation Division. Reel III, Meat Division; Fruit and Vegetable Division; Rodent Division. A brief statistical summary is given with each division.

NEW YORK TUBERCULOSIS ASSOCIATION
MEETING

THE annual meeting of the New York Tuberculosis and Health Association and of the Tuberculosis Sanatorium Conference of Metropolitan New York will be held at the Hotel Pennsylvania, New York, N. Y., March 2. The morning session will be under the auspices of the Sanatorium Conference, Dr. Foster Murray, Chairman, presiding.

"The National Health Program" will be discussed at the luncheon session, held under the auspices of the New York Tuberculosis and Health Association, Dr. I. Ogden Woodruff, President, presiding. Dr. Abel Wolman, President of the American Public Health Association, will discuss the extent and magnitude of the national health program, and Dr. George Baehr, Chairman of the Public Health Relations Committee of the New York Academy of Medicine, will give the viewpoint of the practising physician.

HOSPITALIZATION INSURANCE IN THE UNITED STATES

THE American Hospital Association has announced that almost three million persons in the United States are participating in non-profit hospitalization insurance. Predicting that 500,000 hospital bills, totaling \$25,000,000, would be paid by non-profit organizations during 1939 to the 600 member hospitals throughout the nation, C. Rufus Rorem, Ph.D., of Chicago, announced that the number of participants had increased 100 per cent during 1938.

DISPOSAL OF OIL-FIELD BRINES

AS a feature of its study of the disposal of oil-field brines, the Bureau of Mines, U. S. Department of the Interior, has just published a report on the construction of seven typical oil-field brine-conditioning plants and their operation in preparing brines for subsurface disposal. The investigation is being conducted in coöperation with the Kansas State Board of Health. Such oil-field brines constitute a source of pollution of water supplies.

One of the major problems in the underground disposal of oil-field brines is the clogging of the subsurface formation in the disposal well by suspended matter in the brines. Pretreatment of brines and subsequent subsurface disposal still remain in the experimental stages due to technical and economic problems involved. Consequently numerous types of brine-conditioning systems and methods of brine treatment attaining varying degrees of success have been developed by entering streams draining oil field areas and by passing into shallow water brining formations which may be used as sources of private and public water supply.

These studies, by Sam S. Taylor, C. J. Wilhelm, and W. C. Holliman, have been published as Report of Investigations 3434, "Typical Oil-field Brine-

Conditioning Systems: Preparing Brine for Subsurface Injection." Copies are available without charge upon request from the Bureau of Mines, Washington, D. C.

A.I.C.P. GUIDES FOR NURSES

THE Guides for Public Health Nurses in the Family Health Series, published by the Association for Improving the Condition of the Poor, New York, have been revised.

The A.I.C.P. announces the following Guides for the use of nurses employed by them:

- No. 1. Child Development
- No. 2. Syphilis
- No. 3. Tuberculosis
- No. 4. Cardiac Conditions
- No. 5. Posture

The price is 5 cents each on quantities up to 100, and 4 cents on orders over 100 (plus postage). Address orders to the A.I.C.P., 105 East 22nd Street, New York, N. Y.

MOBILE X-RAY UNIT FOR VIRGINIA

THE Virginia State Department of Health recently purchased a new mobile X-ray unit because of the increasing demand for X-ray service in rural areas.

The truck provides facilities for taking chest pictures, developing films and making the information immediately available to local physicians who have referred the patients to the clinic.

RESPIRATORS FOR BRITISH HOSPITALS

ANNOUNCEMENT has been made that every hospital in the British Empire will be equipped with a respirator. These iron lungs will be furnished by Lord Nuffield, British motor manufacturer and philanthropist, who will turn over one of his factories to the manufacture of this equipment, which he plans to deliver to the hospitals free of charge.

PERSONALS

Central States

CLIFFORD H. GREVES,[†] of the University of Michigan, Ann Arbor, Mich., has been appointed Venereal Disease Statistician to the Michigan Department of Health in Ann Arbor.

DOROTHY ROOD, R.N., Ph.D.,[†] of Columbus, Ohio, who has been in charge of the courses in Public Health Nursing at Ohio State University for the past 3 years, has been appointed Director of Public Health Nursing for Loyola University, Chicago, Ill. Her work will be in connection with that of EARL E. KLEINSCHMIDT, M.D., Dr.P.H.,[†] the Director of the Department of Preventive Medicine, Public Health and Bacteriology in the School of Medicine.

Eastern States

DAVID B. AST, D.D.S.,[†] has been appointed Assistant Director for Oral Hygiene, in the Division of Maternity, Infancy and Child Hygiene, of the New York State Department of Health, Albany, N. Y.

DR. HELEN BALDWIN has been appointed Health Officer of Canterbury, Conn.

DR. SAMUEL S. FARAGO, of Westerly, R. I., has been appointed Health Officer of Pawcatuck, Conn., succeeding the late Dr. WILLIAM A. HILLARD.

DR. CHARLES FLYNN is now Acting Health Officer of Hamden, Conn., succeeding Dr. GEORGE H. JOSLIN.[†]

EDWARD S. GODFREY, JR., M.D.,* Albany, N. Y., has been reappointed for a term of 4 years as Commissioner of Health of New York State.

GEORGE C. SHATTUCK, M.D.,[†] has been promoted from Assistant Professor to Clinical Professor of Tropical Medicine, in the Harvard Medical School and the Harvard School of Public Health, Boston, Mass.

Southern States

HENRY F. BUETTNER, M.D., of the Baltimore City Health Department, was promoted to the position of full-time Medical Health Officer. Since 1922, he has been instructor in bacteriology and immunology in the University of Maryland Medical School.

DR. HUGH G. CLARK, of Lafayette, Ala., has been appointed Health Officer of Chambers County, succeeding Dr. ABRAHAM I. PERLEY, who was awarded a year's graduate study at Harvard University.

DR. JACK A. CRITTENDEN, of Elba, Ala., has been appointed Health Officer of Coffee County, succeeding Dr. WILLIAM A. DODSON, JR., who resigned on account of ill health.

GRADY F. MATHEWS, M.D.,[†] of Tahlequah, Okla., has been appointed State Commissioner of Health of Oklahoma, succeeding Charles M. Pearce, M.D. Dr. Mathews since 1936 has been full-time Health Officer in a 5-county health district in Oklahoma. He is a graduate of the University of Oklahoma and has studied at the Johns Hopkins School of Hygiene and Public Health.

G. FOARD MCGINNES, M.D., Dr.P.H.,* has resigned as Director of the Bureau of Communicable Diseases in the Virginia State Department of Health to accept a position in Memphis, Tenn., as Director of the Venereal Disease Demonstration Project. Dr. McGinnes will also serve as Associate Professor of the University of Tennessee, and as Consultant with the Tennessee State Health Department and the U. S. Public Health Service.

DONALD B. McMULLEN, D.Sc., Head of the Biology Department, Monmouth College, Monmouth, Ill., has been appointed Assistant Professor

* Fellow A.P.H.A.

† Member A.P.H.A.

of Bacteriology, in charge of the Division of Parasitology, University of Oklahoma School of Medicine, Oklahoma City, Okla.

FRED L. MOORE, M.D., C.P.H.,† who for 11 years has been County Health Officer of Sullivan County, Blountville, Tenn., has resigned to become Associate Professor in the Department of Preventive Medicine and Community Health of the Long Island College of Medicine, Brooklyn, N. Y.

J. W. ROY NORTON, M.D., M.P.H.,* of Chapel Hill, N. C., Assistant Director of Preventive Medicine of the North Carolina State Board of Health, has been appointed Professor of Public Health Administration in the Division of Public Health, University of North Carolina School of Medicine.

DR. MARTLE F. PARKER, of Greenville, Ala., has been named Health Officer of Butler County, to succeed DR. CHARLES J. FISHER, who is taking graduate work at the Johns Hopkins School of Hygiene and Public Health, Baltimore.

Western States

MARION W. CASKEY, M.D., PH.D.,† of Lewiston, Idaho, has resigned as Health Officer of the North Central Idaho Health District, composed of Nez Perce, Latah, and Clearwater Counties.

DR. JOHN R. CORKERY, JR., has resigned as Health Officer of Spokane, Wash., to engage in private practice.

CHARLES L. COYLE, M.D.,† formerly of Marshfield, Ore., has resigned as Health Officer of Coos County, to engage in private practice in Grants Pass.

DR. FRED CHARLES HARVEY has been appointed Health Officer of Spokane, Wash., succeeding DR. JOHN R. CORKERY, resigned.

DR. RICHARD N. SHERWIN, of St. Helens, Ore., has been appointed Health Officer of Washington County, succeeding DR. DANIEL C. McDONALD, of Hillsboro, Ore., resigned.

Canada

A. J. DOUGLAS, M.D.,* Chief Medical Health Officer of Winnipeg, Canada, will retire April 1, after almost 39 years as head of the city Health Department.

LASSALLE LABERGE, M.D., of Montreal, Que., was recently appointed Director of the Tuberculosis Division of the Ministry of Health of the Province of Quebec.

DEATHS

J. TREICHLER BUTZ, M.D., D.D.S.,* City Health Officer of Allentown, Pa., died December 22. Dr. Butz was a member of the A.P.H.A. for more than 20 years, and in 1922 was elected a Charter Fellow of the Health Officers Section. He was also a Life Member of the Association, having been elected in 1934.

DR. MATHEW J. SHIELDS, of Scranton, Pa., died January 23, at the age of 76. He served with the Red Cross as a Red Cross first aid instructor from February, 1909, until his retirement in June, 1936. In 1909 he was commissioned a first lieutenant in the Medical Reserve Corps, later serving as captain in the Medical Corps during the World War. In 1924 he was made a lieutenant colonel in the same service.

LUCY P. SUTTON, M.D.,† Associate Professor of Pediatrics at New York University, New York, N. Y., died in December.

* Fellow A.P.H.A.

† Member A.P.H.A.

CONFERENCES AND DATES

- American Association for Social Security. New York, N. Y. April 7-8.
- American Association of Anatomists. Boston, Mass. April 6-8.

CHILD HEALTH FILMS

Entertaining and Instructive

silent and new sound-on film, with voices as clear as a bell and excellent photography, accepted by health authorities as the greatest health films ever produced. Used by schools, State, County and City Health Departments, Medical and Dental Associations, Tuberculosis Associations, Parent-Teacher Associations, and Dairy Councils. Stresses diet, rest, safety-first, exercise, school nurse, Health Department, school examination, immunization and the tuberculin test, correction of deformed faces and irregular teeth, medical and dental examination, and shows effective habits and way to care for the body, mouth and teeth. Information as to sale or rent from: Dr. David Bennett Hill, Producer, Salem, Oregon.

Is the Health Officer Fulfilling His Responsibility in Relation to the Nursing Program?*

GRACE ROSS, R.N., F.A.P.H.A.

Director, Division of Nursing, Department of Health, Detroit, Mich.

TO be given an opportunity to discuss this subject is a great privilege, because the subject is an important and timely one. In trying to reach an answer it seemed better to find one based on the health officer's report of his own practical performance in relation to the nursing program at the present than one based on anybody else's opinion. Eighty-two questionnaires were sent to health officers in cities having a population over 100,000. Sixty, or 74 per cent, replied promptly. Of these, 52, or 63 per cent, presented comparable information and were received in time to be studied. This information is in reference to 2,937 nurses, about one-fifth as many as used by Marian G. Randall in her splendid report.¹ This is a study made in 1937 for the National Organization for Public Health Nursing and is highly recommended to those health officers who wish a comprehensive, country-wide view of this subject. Five health officers who replied buy their public

health nursing service from an already well established, unofficial public health nursing agency. As they function quite independently of the health officer, their data, and also those of the Detroit Health Department, have not been included here.

All but 2 health officers, *i.e.*, 49, provided budget figures. Of these, 45 show a per capita rate for health work of less than one dollar, and 4 a rate of over one dollar. The information requested was limited to the several health services which are included in the Annual Health Conservation Contest, usually called the preventive medical services. The figures given indicate great differences in the number of official public health nurses considered necessary to carry out these services. The amount of money which communities are willing to pay for health may be one reason for this variation. The ratio in 52 cities varies from one official public health nurse for 4,000 to one nurse for 41,000 of the population. Eighteen per cent had one nurse for 5,000 or less, 4,000 being the minimum; 55 per cent had one nurse for 5,000 to 10,000; 14 per cent had one nurse for 10,000

* Read at a Joint Session of the Health Officers and Public Health Nursing Sections of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 27, 1938.

to 15,000; 14 per cent had one nurse for 15,000 and over, one of the latter being 32,000, another 41,000.

The importance of the public health nursing program to the health officer is probably reflected better in the percentage which his nurses bear to his total personnel. Forty-six cities gave answers which show the following: In 20 per cent of the cities, less than 25 per cent of the staff are public health nurses; in 85 per cent, the nursing staff is less than 50 per cent of the total; in 15 per cent, the nursing staff is 50 per cent or more of the total personnel. One city runs as high as 73 per cent; another, 80 per cent. It is interesting to note that in the cities having more than one dollar per capita to spend, the percentage of nursing staff varies from 22.9 per cent to 80 per cent.

The backbone of all public health nursing and the secret of its effectiveness is the preparation of the nursing staff. The health officer predetermines the success of his nursing staff when he accepts the qualities and qualifications which each nurse possesses. We are glad that it has not been necessary for each health officer to make a study individually of this problem, because the National Organization for Public Health Nursing has already done so. The standard known as "Minimum Qualifications for Those Appointed to Positions in Public Health Nursing"² is the result of this very careful study and it was accepted by the American Public Health Association in January, 1936. Because it is recognized as a minimum standard, which is already surpassed by a few departments, it is to be hoped that fewer official health departments will continue to fail in meeting it than is true at present. Only 23 per cent meet these minimum standards; 42 per cent reply that they do not; and another 35 per cent failed to answer.

A study of the questionnaires un-

covers a possible way through which a change might be accomplished. Forty-six, or 69 per cent, of the departments are under civil service. Sixty-four per cent of those departments with less than minimum standards are under civil service. It is obvious that improvement should come through selling the facts to civil service commissions.

In reading over the civil service requirements presented, it is seen that their regulations vary from requiring an "R.N.," which may mean no standards which could contribute much to public health work, to "college matriculation and a certificate in public health nursing or its equivalent." Some lay great store by the "R.N." In most states the "R.N." standard is not even a minimum standard for bedside nursing. It is a compromise reached between the supporters of those who wish the community to be properly nursed and the supporters of those who wish to prey on the community. In many states the "R.N." does not mean that the nurse has had the college education so desirable for a public health background, nor even a first rate high school education. As a matter of fact, at present there are laws in 40 states which require the "R.N.," but only 26 of these include a high school education as a necessary means of obtaining it.³ The "R.N." does not mean that the nurse has been graduated from an affiliated hospital wealthy enough to provide her with adequately prepared teachers nor having patients enough to provide her with sufficient experience even in the limited services which it offers. In most states it is not necessary for the nurse to have practical experience in the care of communicable diseases, tuberculosis, syphilis and gonorrhea, or in mental nursing, and many nurses are still found to be inadequately prepared to do orthopedic nursing.

We realize that for financial reasons

the need for hospitals to exploit student nurses is still acute. That, however, is no reason why the public health field must accept the graduates of those schools of nursing which still fail to provide student nurses with the fundamental preparation upon which later good public health nursing can be built. As an example of the difficulties encountered, in Michigan, whose state law does not require a high school education, the nursing schools have all voluntarily adopted the high school as a minimum standard; yet the following deficiencies in experience, upon which public health work is built, are still to be found: 69 per cent of the schools do not offer actual experience with tuberculosis patients; 60 per cent with other acute communicable diseases; 63 per cent with nervous and mental patients; and as in other states, information concerning syphilis and gonorrhea is not even collected. It is therefore not surprising that 72 per cent have not been exposed to public health experience in any form. The health officer needs to correct the ideas of the Civil Service Commission and to help them understand that his nurses must have adequate fundamental undergraduate experience in these necessary fields, no matter what the state is willing to call them. In other words, the minimum standards of the National Organization for Public Health Nursing are basic requirements for good public health nursing in every state and there cannot be good public health nursing as long as Civil Service Commissions adopt anything less than these minimum standards.

It is most heartening to know that these N.O.P.H.N. minimum qualifications have been adopted by some Civil Service Commissions at the request of health officers, in fact, 33 per cent of the departments using these standards are official departments under civil service. Health officers will find helpful

material for this purpose on page 22 of Miss Randall's book already referred to. One health officer describes his experience in these words, "On last requisition a copy of the N.O.P.H.N. requirements was sent to civil service commissioner and requested that it be followed. It was." These health officers, real leaders, deserve the greatest admiration and praise of every public health nurse.

A word should be said concerning the personality and background of the public health nurse. It is certain that public health nursing is not promoted by the health officer who accepts inferior nurses and then finds it impossible to treat them with respect. Dr. John E. Gordon, Professor of Preventive Medicine and Epidemiology of the Medical School of Harvard University, has recently returned from Central Europe where he was directing special studies for the Rockefeller Foundation. In describing the nurses of the Balkans, he speaks of two kinds, those who dominated the field before the war and those since the war. He mentions the former as coming from the kind of homes which usually provide the maid service of any community and the latter as coming from the kind of homes which produce professional people. It is a very hopeful sign when a distinguished member of the American Public Health Association is aware of and sensitive to such far-reaching differences.

It is very encouraging to find that 40 per cent of health officers expect their nurse directors to spend some time in studying the qualifications of the nurses available, and that after discussing the facts with them the health officers employ the nurses in relation to the facts. Five health officers report political interference even though they are under civil service. One puts it "trying to tell me which one in three."

Of the 52 health departments only

28, or 54 per cent, have a nurse to direct the nursing program as a whole. That anybody can direct a public health nursing staff better than a well chosen public health nurse properly prepared for that responsibility is hardly worthy of our discussion. Public health nursing is a practical educational program which uses the content of the nursing course and the technics of public health nursing to put over health information and to teach the public. The person who can direct nurses best in the use of these tools for this purpose is a nurse who has been instructed in them.

There needs to be unity and oneness in purpose to make a service strong and conscious of its group responsibility and it is achieved best by a concentration of direction and leadership. The only person who promotes all phases of the nursing program without prejudice is the person who is not limited to any one part of it. That is the nursing staff director.

The health officer is entitled to the best prepared director of nurses that can be found. He should then lend an ear to all the progressive suggestions she presents for his understanding and support and actively to promote all that improves the quality of his nursing service. It would be fair to say that the health officer has not done the best for his service when he has engaged a director of nurses who has no progressive ideas to offer for his support.

It cannot be said that the salaries of directors, on the whole, stimulate nurses to pursue the necessary additional postgraduate education, because most of them are inadequate. Seventeen, or 60 per cent, of those departments having a nurse director give yearly salary figures. They range from \$1,800 to \$3,600, with one exception, \$6,500. Only 5 have a salary of \$3,000 or more, and 11 have less than \$2,800. The minimum qualifications for directors include a college degree as desirable edu-

cational preparation; graduation from a hospital school which has available 100 patients daily and experience which includes all the extra services listed above; at least one academic year in public health, theory and practice of supervision; 2 years of public health work under qualified supervision; several years' experience as a supervisor and if possible as an assistant director. She should have superior administrative ability and qualities of leadership. Also, in the interest of the department many demands which cost money are made upon the director and these make these poor salaries poorer because, while she cannot afford to finance them, as a director of nurses she cannot afford to miss them. In the light of these facts and the salaries quoted it does not appear that many health officers appreciate their responsibility to the head of their nursing service.

Regardless of the splendid public health preparation which some health officers require of nurses before giving them a position, supervision is still an essential. Each health department has its own particular policies, technics, rules and regulations, in which the nurses must be instructed. Constant improvement in department methods makes further changes necessary, and in every worth while occupation stimulation and inspiration must be given attention. The well prepared supervisor is the answer. Since her importance has become better appreciated and because supervision now includes several new services which have been added in recent years—nutrition, social diseases, mental hygiene, and others—the old accepted standard of 1 supervisor to each group of 10 nurses has proved to be inadequate. In view of this, it is disappointing to find that 67 per cent of the health officers are not able to report that they provide their nursing division with even this minimum, insufficient amount of supervision.

Two staffs of 60 and over have only 2 supervisors or 30 nurses apiece. Ten staffs ranging from 3 to 21 have no supervision whatever. These are not errors because while other salaries are given supervisors' salaries are not given.

Most administrators find that nurses on the whole make poor clerks and nurses accept this criticism. It is money wasted whenever a nurse's salary is used this way because clerical assistance should cost less and nurses should be doing the health work which otherwise will go undone. It may be easier to add nurses to the staff than it is to add clerks, but whatever the explanation it is obvious that most nursing staffs would do better and more nursing work if given enough clerical assistance to eliminate at least the routine clerical work. Especially is this true in clinics. Forty departments gave replies to this question. Two had no clerks whatever. Of those remaining, 45 per cent had 1 clerk for 10 nurses or less, and 15 per cent had the admirable record of 1 clerk to 5 nurses or less. That leaves 55 per cent that have 1 clerk for 10 nurses or over; 20 per cent of those are for 20 nurses or over. One staff has the rate of 1 to 120.

In regard to staff education, thoroughgoing programs of continuous staff education of college level are found only in 11 of the 51 cities answering and where these occur there is a full-time nurse director. Fifty per cent of the departments had no program of staff education in spite of the fact that the basic requirement in all of them is less than the acceptable minimum. Thirty-five per cent had some kind of program but there seems to be no planned program or definite objective in view. Where a certificate in public health nursing is the requirement for acceptance the need for continuous staff education may not be quite so urgent, but even here, with the constant growth and change which take place in the public health field, it

is a question of how long the certificated nurse can remain useful when no continuous staff education program is offered to her. Three departments have monthly or "occasional" lectures. Four have "the state's program" and it is to the credit of 5 that they have a continuous staff education of college grade. One health officer who has a staff of 29 certificated nurses but no nurse director says he has weekly conferences and "more not necessary."

A study of the salaries given shows no definite convictions on the part of health officers in regard to them. It would be expected that the range, regardless of the prevailing regional induction salary, should be, for similar work, the same the country over. We find even within the same state a difference in the salary range which varies from \$180 to \$899. Under civil service induction salaries vary from \$1,170 to \$2,100, and in departments not under civil service from \$1,200 to \$1,500. A few departments which have adopted the N.O.P.H.N. minimum standards offer only \$1,200, and a few departments which have no minimum standards offer an induction salary as high as \$1,840. One commissioner states "We hire nurses at the regular price when occasion demands," but he did not quote "the regular price." Only 23 per cent of the departments offer annual increases. An additional 17 per cent offer them at 3 or 5 year periods or have temporarily suspended them. Sixty per cent showed no increases or left the question unanswered. One health officer has raises every 6 months, a plan which has many advantages.

If a profession wishes to draw to it those best prepared to make a contribution, it would seem that there should be some relationship between the salary offered by it and the preparation which is offered by the applicant. There is very little of such relationship in official public health nursing. Of

the 35 departments under civil service, 17, or 49 per cent, left blank the question, "Is a higher salary offered to nurses who have special preparation?" Fifteen, or 43 per cent, answered "no" and only 3, or 5 per cent, "yes." One of these was qualified by the statement, "only with the permission of the mayor." Of the 17 not under civil services, 59 per cent did not answer, 29 per cent answered "no," and only 12 per cent answered "yes." So, regardless of the system, in less than 10 per cent of the departments have the salaries any relation to what the nurse can contribute. It is a pleasure to add that one commissioner said the idea "was approved" and another that it "was contemplated."

It is crediting nurses with more altruism than they possess to suppose that salary is not an important matter to them and that they are so eager to serve the community well that they will spend hundreds of dollars for additional education on which they expect no financial return. If it could be known that nurses who would obtain at least certificates in public health nursing would receive higher salary and recognition, more nurses would get them. Staff members would then know what they were doing immediately they started to work. At the present time, those who criticise the quality of public health nursing speak as though all employed public health nurses knew what they were doing. Of the 52 departments, only one demands that its nurses know public health nursing on acceptance. All the rest accept nurses with the minimum standards or less. So, strictly speaking, a just criticism of nurses' work is possible only in this one department.

There are some other less important points, discussion of which might prove helpful, but time does not permit it.

To summarize, some health officers are fulfilling their responsibility ad-

mirably in relation to the nursing program and some admirably only in some respects. There are ways however in which many others could help a great deal more: first, to realize that it is an impossibility to get the right kind of service from their staff unless every nurse on it has the right background, the right educational and professional education, the right kind and amount of public health nursing preparation, and the right content of health information. If these are all obtained before coming to the staff, so much the better; if not, it must be understood that the nurse will be on the staff a long time before she thoroughly masters her teaching job. Second, a nurse already prepared as a public health nurse should be paid according to what she brings to the department. She is a specialist and as in every other profession her additional education and experience should be recognized and compensated. Third, it must be remembered that nurses are human like everyone else. All the aids to sustain morale, like recognition for unusual service and increases in salary, and all those aids to improvement in work, like programs of continuous education and adequate direction and supervision, are indispensable.

It has been said that no division of nursing can rise above the level of performance set by its health officer and it should also be said that no division of nursing will get far without his active and understanding support. The quality of the public health nursing program in official agencies country-wide is, in the last analysis, in the hands of health officers; if it is to become grade A only they can decide.

Administrative Problems in a Delivery Nursing Service*

W. F. WALKER, DR.P.H., F.A.P.H.A., AND
E. P. BOWERMAN, M.D.

*Director, Division of Health Studies, The Commonwealth Fund,
New York, N. Y.; and Health Officer, Gibson County
Health Department, Trenton, Tenn.*

IN 1935 a study of obstetrical practices and facilities for maternity care was made under the auspices of the Gibson County, Tenn., Medical Society. Among other things, this study recommended that a delivery nursing service be organized as an adjunct to the existing public health program which had been carried on since 1922. The purpose of this paper is simply to indicate the administrative problems met in initiating and carrying on this service and how they were handled.

A WORD ABOUT GIBSON COUNTY

Gibson County, an essentially rural area, is in west Tennessee. It has a population of 49,000, of which 21 per cent are Negroes, and 23 per cent live in the three towns with populations ranging between 3,000 and 5,000. The county is moderately well to do for west Tennessee with an estimated per capita spendable money income of \$211 annually.

At the time of the study (1935) the personnel of the health department consisted of a health officer, an assistant

health officer, a supervising nurse, 5 staff nurses, a sanitary officer, and 2 clerks. The staff was giving due consideration to the acute communicable disease problem of the county, providing the usual services for infant, preschool and school hygiene, and, through special activities, making an attack upon both syphilis and tuberculosis. Due to the health officer's personal interest and training, possibly slightly greater emphasis was given to maternity hygiene service than otherwise would have obtained in the department prior to the organization of this formal service. The county health department, working in close coöperation with the local physicians, provided, in 1937, antepartum nursing supervision for 51 per cent of the mothers and instructive postpartum care for 52 per cent.

Gibson County is unique among rural southern counties with a large colored population, in that there are practically no midwives. Of the 800 births which occur annually, 93 per cent are delivered by physicians in the home, only 1 per cent occur in hospitals and about 6 per cent are attended by midwives, grandmothers, or convenient neighbor women.

The study of maternity care already referred to revealed that an appreciable

* Read at a Joint Session of the Health Officers and Public Health Nursing Sections of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 26, 1938.

number of maternal deaths, stillbirths, and infant deaths might have been prevented had the physician had the advantage of a trained person to assist him. For this reason, and to make the health department's service to the case continuous rather than interrupted at the most crucial time, the delivery nursing service was organized.

The county health department seemed to be the logical agency to provide this service since it was well thought of by the public and physicians and was already providing antepartum and postpartum nursing service to half the mothers.

REGULATIONS

It was early recognized that there would have to be very definite regulations governing the use of the service and that these must be understood and accepted by the local physicians in order to avoid misunderstanding and to reinforce rather than undermine previous teaching as to the value of antepartum and postpartum care.

The entire plan was, therefore, discussed at the regular meeting of the medical society by the health officer and the following principles worked out:

1. The service is available to all doctors practising in the county for patients living in the county.
2. Patients who receive the delivery service must have been under antepartum supervision for 4 months—except in case of emergency.
3. The service is provided for any case in the county in the event of a complication in which nursing assistance is necessary, regardless of the duration of the antepartum supervision.
4. Both patient and doctor must desire the service.
5. The doctor must not leave an obstetrical case for the nurse to watch while he attends to the rest of his practice. In general, the nurse accompanies or follows the doctor to the home. When he leaves, she leaves.

Experience has shown that the regulations are both necessary and sound. Success in their observance and general

acceptance by the profession was no doubt considerably augmented by extension teaching in obstetrics under the auspices of the State Medical Society as a part of its program of postgraduate education. This course of lectures, which laid particular emphasis upon antepartum care and asepsis, was given in the county just as the delivery nursing service was being launched.

Those familiar with the public health work in Gibson County were agreed that the generalized program already in existence should be continued and the delivery service added to it with as little change in emphasis in other fields as possible. This required additional nursing staff and equipment for the county health department. On the basis of $2\frac{1}{3}$ births a day, on the average in the county, and taking into consideration both uneven daily distribution and that the health department might well expect to assist in at least half of the cases, it was believed that a minimum of 2 nurses would have to be added to the existing field staff of 5. It was also recognized that not all deliveries would be given nursing service and that this additional staff would very likely be adequate for the case load which ultimately developed.

TRAINING OF PERSONNEL

Though the field nursing staff in the county was well trained, at the time none had had any special training in obstetrics. Arrangements were made for a special course for the supervisor and one staff nurse at the Chicago Lying-In Hospital. Approximately 1 month was spent in in-patient service acquainting them with modern obstetrics under the most favorable conditions and 2 months were spent on the home delivery service which offered many of the difficulties that would be encountered by the nurses in rural areas. Having in mind the routines and procedures which were current at the

Chicago Lying-In Hospital, the local staff, with aid from the state department of health and others, worked out routines which were adapted to local conditions and which experience has shown can be carried out satisfactorily in a rural community. These nursing technics were then taught to the remaining members of the staff by office demonstration using a large doll and subsequently through supervised deliveries.

EQUIPMENT

One of the recommendations of the maternity study was that the health department offer sterile equipment for the use of local physicians in home deliveries. A sterilizer was installed and a list of equipment and supplies was set up which the nurse would carry to the home. They included the items necessary for the conduct of normal labor, emergency equipment, and medications. The details of the sterile and other equipment which were carried with the costs are available on request. The sterile supplies required on every case were wrapped together and carried in a fiber case. The remaining equipment and medications are carried in a leather bag. This includes scrub-up material, intravenous set, sterile packing, tracheal catheter, records, and medications.

In setting up the list of sterile supplies due consideration was given to items which the mother would have available in the home and particular attention was given by the nursing staff to seeing that these materials were available well in advance.

It was intended that the physicians should provide all medications, but to meet emergencies which are bound to arise, caffeine, adrenalin, ergotrate, and pituitrin are carried. It was also intended that the doctors should carry, in addition to their own instruments, suture material, though experience has

shown that it is desirable to have sutures and needles available.

Before initiating the delivery nursing service, the antepartum and postpartum programs were altered slightly in order to insure better continuity with the partum service. Copies of these outlines of nursing procedures are available on request.

SCHEDULE

The most difficult problem to be handled in setting up a delivery nursing service is scheduling this activity to fit into other parts of the program. If the service is to be successful, a nurse must be available at all times, which means shifting the program from an 8 hour to a 24 hour base, and from a 5½ to a 7 day week. It was realized from the first that, if this service were to have any value in improving general community relationships and influencing other fields, it must be set up as a function of the generalized service with all of the staff nurses carrying delivery service at some time. Furthermore, if the load which was anticipated materialized, two nurses could not possibly carry it as a specialized service. Even when scheduled as a part of a generalized service two alternatives were open: (1) to have each nurse carry the deliveries in her own district, which would provide greater continuity of service but lead to some embarrassment to the regular program through interruption; or (2) to have one or two nurses on call each day and relieve them in whole or in part from their district responsibilities for the day on delivery duty. This latter plan was finally decided upon as it was felt that it would:

1. Promote unity of purpose in the nursing staff
2. Avoid wasted time in case no delivery was in progress as the nurse on second call could proceed with other phases of her program
3. Would, because the value of this service was easily apparent to the public, strengthen

the nurse's approach and contacts with the community

4. Would place a definite limit on the continuous hours of obstetrical duty and thereby lessen physical strain.

Under this plan, two nurses were always on call, one on first and one on second call. If we designate the 7 nurses as 1, 2, 3, 4, 5, 6, 7; nurse 1 on first call remains in the office during the day until a call is received. Nurse 2 on second call does field duty nursing until the first nurse 1 is called out. This is determined by periodic telephone calls to the office by second nurse 2. When nurse 1 is called out, nurse 2 returns to the office in order to be ready for a second case. At night (4:30 P.M. to 8:00 A.M.) both nurses must be within reach of the local telephone operator to whom they report each evening at the close of the office. The nurse on second call does not take a case unless the first nurse at the time is busy at another delivery. After a 24 hour tour of duty beginning at 4:30 P.M., nurse 1 goes off duty completely for 24 hours, nurse 2 becomes first call nurse, and nurse 3 becomes second call nurse, and so on.

In this instance there were 7 nurses to schedule and the tour of delivery service would have fallen on the same day each week if they proceeded in rotation. To avoid this each nurse was given 1 week without delivery service every 7 weeks. In case of sickness or vacation, the supervising nurse fills in for the staff nurse. Ten months' experience has proved that this schedule will work.

RELATIONS WITH PRIVATE PHYSICIANS

On the whole, the delivery service has been welcomed by the private physicians. It is a health department service of direct and tangible assistance to the physicians individually and collectively in their private practice. As might be expected, some are inclined to

view the service simply as nursing assistance furnished them and give little thought to the public health education which is essential to the best results. A few are inclined to criticise the requirement that cases be registered for medical and nursing antepartum supervision by the 5th month. While it is true that the doctors are frequently called to cases who have not been under antepartum supervision, and while nursing assistance would be desirable, the better men appreciate the long time advantage of this regulation. Experience thus far indicates that many more cases are reporting earlier for antepartum care than formerly and that the delivery service functions more smoothly in those cases who have had antepartum supervision and who have made suitable preparation for the baby's birth.

Some physicians have criticised the service because the nurse arrives too late. We are still of the opinion, however, that it would be both unwise and uneconomical to provide nursing care for a longer period than the physician is in attendance, as this would inevitably lead to situations in which the nurse would be forced to act as a midwife. The fact that the service can work almost perfectly so far as the doctor is concerned has been demonstrated by the physicians who have been the most extensive users of the service and who are in the main the best obstetricians. They, in general, determine the stage of labor before calling the nurse and are completely coöperative in their attitudes.

To determine with some definiteness the medical attitude, a brief letter and questionnaire were sent to the 43 physicians practising in the area. Of the 30 men who replied, only one expressed any doubt as to the worth-whileness of this service as a function of the health department. Yet, he admitted its advantages to him in his private practice.

Among the advantages which are cited were the following:

"It permits me to do a safer and better delivery. It makes a favorable impression on the patient to see me try to keep a sterile field. It encourages the patient to come in to the doctor earlier. It makes more of them come in for postpartum examinations."

"Makes possible early antepartum care; Kahn reports in early pregnancy; better able to educate the public to modern technic of delivery rather than blind deliveries under sheets; better aseptic conditions; nurses valuable in complicated deliveries."

And finally the physician who has probably used the service most and has the largest number of deliveries in the county:

"I have never before in my life or practice had the opportunity of using a nurse in delivery work and I have found it the best help to both me and my patients and I hope it will continue as long as I continue in practice."

These opinions of competent men are typical of the feeling of those doing the major obstetrical job.

Instances have occurred of unanimous endorsement of public health programs by physicians where they were paid a nominal fee for services rendered. It is gratifying to see that in this instance a service primarily designed to assist the doctor to render better obstetrical care without any personal compensation received wholehearted endorsement.

PRACTICAL DIFFICULTIES

We should like to mention a few practical difficulties encountered. The reaction of the nursing staff to this radical change of program presented a serious problem for a time. Weather and roads have had a considerable bearing upon this reaction, for, although Gibson County is a progressive and prosperous agricultural district, many of its roads are only graded dirt which in winter or rainy weather become a sea of mud making it impossible at times to reach

some homes by automobile. Insanitary and poorly heated homes add to the unpleasantness of the duty. These physical factors, the unusual routine of being on call, the occasional long periods of continuous duty, have frequently made a nurse wish that she were somewhere else where a delivery service was not a part of the program. This reaction on the part of the nurse was much more intense when the service was just begun than after 10 months' experience.

It is possible with the schedule as now arranged for a nurse to have 56 hours of continuous duty as an 8 hour day of field service always precedes 48 hours on call. Though this limit has never been reached, it has been approached on three occasions. This situation could, of course, be relieved by having a day of field duty intervene between the period of second and first call or by having the delivery service day begin in the morning instead of at night. It is felt by the staff, however, that this would add complexities to the schedule and that they would prefer to have consecutive delivery service and consecutive field time.

The schedule of field work has of necessity had to be adjusted to provide for the priority demands made by the delivery service. This has necessitated the planning much further in advance of clinics, community meetings, school examinations, and similar services. With the schedule of delivery duty planned for at least 3 months in advance, however, the difficulty in this field has been minimized. By actual count, the time devoted to field duty by the staff because of the days off is slightly less than before the service was inaugurated. It is still too early to draw any final conclusions as to whether or not this will seriously affect the program. It seems probable that even with the reduced number of visits, however, better relationships established in the home be-

cause of this service will increase the effectiveness of other visits made.

Because of the regulations set up requiring the registration of cases before the 5th month of pregnancy, except for people moving into the county and complicated cases, there has been some complaint on the part of physicians that the service does not reach all of the individuals needing it. Experience to date indicates that the service has been used most frequently by the more prosperous and better informed people and that no adequate means has thus far been found to bring the group with less initiative and forethought under supervision.

As is natural on a staff of this size, that desire for professional advancement, opportunities for more desirable positions, etc., lead to staff changes. This has necessitated careful selection of candidates for staff appointments to insure their willingness to undertake the service, and also a continued program of staff education.

SUMMARY

In the first 10 months the department attended 305 deliveries resulting in 293 live births, 12 stillbirths, no maternal life was lost, and but 5 infants died within the first month. The staff has devoted a total of 1,804

hours to this service, an average of 5 hours and 50 minutes per delivery, which includes staff nursing time, time spent by the supervisor devoted to staff training and answering of false calls. Fifty-three per cent of the calls were attended by the nurse on first call and 47 per cent by the nurse on second call. The staff has given 1,336 hours overtime service and has been allowed 2,024 hours extra time off in compensation—virtually time and a half for extra time service.

In the light of this experience it seems clear to us that:

1. A delivery service can be set up as a function of a county health department and have its work appreciated by the public and whole-heartedly endorsed by the physicians

2. Though the addition of such a service to a health department's program where there is a reasonably adequate nursing staff will influence to some degree time and emphasis placed upon other parts of the program, it has not, in this instance, in the opinion of the health officer and staff of the state health department, seriously interfered with the programs in other fields

3. Though the initiation of a delivery nursing service places a burden upon the public health nursing staff which they have heretofore been unaccustomed to, it is evident that the schedule can be so arranged as to work no undue hardship upon the staff or make the work so unattractive to the public health nursing profession that insuperable difficulty is found in finding suitable personnel.

DISCUSSION

W. C. WILLIAMS, M.D., F.A.P.H.A.

State Commissioner of Health, Nashville, Tenn.

DRS. Walker and Bowerman have presented a very comprehensive discussion of the local administrative problems encountered in the planning and conduct of an obstetrical nursing delivery service. The program as outlined is of interest, not only from the standpoint of local considerations, but

also from it we hope to determine the most feasible procedures, if any, that may be utilized in setting up similar service elsewhere. It is particularly desirable that we be able to evaluate not only the results of this special activity in terms of public service and decreasing maternal morbidity and mor-

tality but that we give careful consideration to the possible ways in which the service may be extended to areas where the population and area per nurse is not so favorable as in Gibson County where each nurse is not required to be on first call more than once a week.

The question of a *special* versus a *generalized* service is also worthy of some consideration. Obviously it would not be possible for the small health department to plan a very definite program—even the department with a staff the size of the Gibson unit could not plan other work in advance unless there was some systematic method of scheduling assignments for this service. While it can truthfully be said that the program is carried on by the general nursing staff and that there is no apparent interference with the general nursing program, it is in reality a special nursing service to which each nurse of the staff of eight contributes a specified and periodic pro rata of time. We are not yet in position to chart a course

to be followed by the local departments with an admittedly inadequate nursing staff.

That the service is popular with the general public there is no doubt. The physicians utilizing it have only commendation for the assistance given. The skeptical and disturbed attitude of the nursing staff at the beginning of the program has been largely dissipated. There is some evidence that the work does appeal to a good percentage of the nurses just entering the public health field as well as to the more experienced group that had grown accustomed to daylight saving work hours only. The preliminary analysis of infant and maternal mortality indicates that the health and lives of mothers and babies are being conserved.

To say the least, we are digging for solid rock upon which our future program will be built. Perhaps we have already laid the foundation for the structure that is surely to come as a part of a hitherto unprovided service.

A Critical View of Nurses and Nursing Programs*

FELIX J. UNDERWOOD, M.D., F.A.P.H.A.

Executive Officer, State Board of Health, Jackson, Miss.

PUBLIC health nursing may be defined as an organized community service rendered by specially and adequately prepared graduate nurses. It includes the interpretation, application, and teaching of hygienic, medical, nursing, and social procedures to promote health, to prevent disease, and to stimulate correction of defects or conditions affecting healthful living.

A clear concept of the status of public health nursing in the administration of public health and its relation to other aspects of the modern health program is essential to sound and effective performance.

Public health nursing plays a vital part in almost every activity of health agencies and requires expert public health nursing guidance.

Factors needed in the development of an effective public health nursing service are a compact administrative organization, adequately qualified personnel, clearly defined objectives, promotion of better service through public health supervision and consultations, and blending of the program with other health activities.

Public health nursing is necessarily a coöperative undertaking. Under

whatever auspices it may be organized, it must be developed with leadership of the medical profession and in close relationship to the work of teachers, social workers, institutions or agencies within the social, civic, and health fields, and particularly to official health activities and medical practice.

The health officer is recognized as the official leader in the health work of any community, responsible for the execution of a health program pertinent to local needs and one which meets accepted standards of public health practice coördinated with the state health program. The official public health nurse must act with his guidance and leadership.

It is essential for the medical director and the public health nurse to have a mutual understanding of policies pertaining to the objectives of the joint health service and its potential growth. He should delegate to her the responsibility for the development of the public health nursing details and technics. She in turn must keep him informed of public health nursing activities and consult him relative to the constructive development of her part of the program.

The wise health officer will expect the public health nurse to use initiative and will refer to her matters pertaining to public health nursing.

Careful consideration must be given

* Read at a Joint Session of the Health Officers and Public Health Nursing Sections of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 27, 1938.

the point where she in turn seeks the counsel of the health officer and abides by his decision. In other words, the public health nurse should never, in her desire to develop the general program, assume prerogatives belonging to the health officer. She may and frequently does by various methods influence his decision, but woe unto her if he interprets this as an intention to plan his program.

Sometimes in her zealous endeavor meticulously to perfect a program, she may acquire the habit of harping on petty difficulties which arise and which will often adjust themselves, at the same time missing the opportunity to encourage him by calling attention to constructive accomplishments.

The public health nurse must be informed and teach as she works, about personal, home, and community health, maternal and child health, nutrition and growth, communicable disease care and control, also social and mental attitudes and adjustments. She works with health officers, private practitioners, and personnel of agencies furnishing medical, civic, and social services. She also contributes indirectly to phases of sanitation, laboratory research, and vital statistics.

Field visits form an important item of the service. In the home as the public health nurse renders service, an opportunity is given to study the family as a whole in its environment, the purpose of the visit being threefold: to interpret and evaluate conditions relating to health problems, to render health service, and to stimulate health education.

By group instruction to various types of audience, the public health nurse multiplies her educational efforts, magnifies the importance of health, and popularizes health precepts. The public health nurse augments the quality of her work to the degree that she increases her teaching skill. She must be able and

desire to stimulate interest in public health. She must understand and employ principles of positive teaching. She must adapt materials to the limitation of the learner and speak in terms which will be understood and utilized. She must acquire the habit of teaching while rendering service, use the psychological moment to vitalize and drive home facts, and as indicated give a touch of drama to arouse interest. After initial instruction a competent teacher summarizes to bring out vital points; also in order to form a basis for future teaching, she evaluates what the individual or group received from the instruction given.

Methods of evaluation employed by the public health nurse include study and interpretation of growth in information, in skills, in development of interest, in improved health and living conditions, and in better understanding of patrons as to their share and responsibility in the development of individual, home, and community health.

A sympathetic understanding must exist between teacher and student with special effort on the part of the teacher to discover the interest and needs of the student.

A successful public health nurse cultivates habits of continued growth, attends and participates in staff conferences, seeks aid from advisory service, reads professional and other good literature and takes advantage of advanced university training. This leads to a better understanding of the relation of public health nursing to society at large and the part not only played by the nurse but by the people served.

As the public health nurse becomes expert she plies her art with increasing skill. She influences the thoughts and emotions of those she serves, she calms and stabilizes, she inspires and motivates. In turn she is sustained by the absorbing work so full of human comedy, tragedy, despondency, and

hope. She develops reserve power, orderly thinking, deliberative planning, and disciplined emotions. She cultivates tolerance toward approved current change in trends and technics, and by coördinated efforts fuses technical and professional services into family and community life. When she thus

integrates her work into the whole program her influence extends in ever-widening circles.

The test of the activities of the public health nurse is measured by the degree of acceptance and execution, on the part of the patrons, of her health teaching.

Possibilities and Means of Improving Dental Conditions in the United States^{*†}

GUY S. MILLBERRY, D.D.S.

Medical Center, University of California, San Francisco, Calif.

IMPROVING dental conditions in the United States I assume means preventing dental disorders in children with the hope that as they reach maturity they will have healthy mouths and sound teeth, functioning normally and with comfort, which they may retain throughout life. On this subject I present a dental educator's point of view.

Improving dental conditions in bygone centuries consisted chiefly in relieving pain. Sporadic attempts in restorative dental art are recorded. About 250 years ago mechanical procedures came into vogue and the esthetic phase also gained some recognition. Only the wealthy or royalty received attention.

Complications arose because of biological unknowns. Then, with the advancement of biological and physical science and progress in technical skill and art, dentistry came to be recognized as a profession. Still the emphasis was laid on restoration and replacement.

At the beginning of the present century, dental faculties considered bac-

teriology of enough importance to warrant its introduction into their curricula. Putrefaction was known but not fully understood until this science brought forth the explanation. Other sciences—pathology, physiology, anatomy, biochemistry, metallurgy, and chemistry—added their contributions to the changing course of study.

About 50 years ago the preventive aspects of dental service began to be discussed and programs were initiated, notably in Strassbourg, Germany, and in Rochester, N. Y. As related to school children in America, this means of improving dental conditions developed slowly until 1910 when it swept from east to west across the country like an epidemic.

In many places the dental schools took an active part in this movement. Besides their participation in the organization of school dental clinics and in making school surveys, the preparation of persons to render more and better service in preventive dentistry was undertaken. The first courses for the training of dental hygienists were organized by Dr. A. C. Fones, of Bridgeport, Conn., in 1913. The idea spread until there are now 19 institutions offering instruction in this field and 32 states have licensed these hygienists.

* Read at a Joint Session of the Child Hygiene and Public Health Education Sections and the Oral Health Group of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 28, 1938.

† See also Editorial on page 375 of this issue for comments and varied opinions on this subject.

At first 1 year of high school constituted the admission requirement, followed by 1 year of professional training; a certificate was granted to those completing the course. Admission requirements were advanced gradually in some institutions to high school graduation, followed by 2 years of professional training, again leading to a certificate. Now in the University of California, 4 years of collegiate training are required for graduation and a degree of Bachelor of Science is granted. These trainees are health educators, supplementing in some instances their health education program with a prophylactic service.

Many dental hygienists are employed in private offices, where the educational program, if carried on at all, is individual. Office duties consist chiefly in periodic prophylactic service for adults, which has value in preventing the recurrence of dental disease. More can be accomplished in the prevention of dental disease by rendering prophylactic service to children at frequent intervals and they should be considered the most important group in the private practice clientele.

The health education programs which have been developed in the schools by dental hygienists have not accomplished all that was hoped, although some of them have been more efficacious than other types of programs. Hawaii is our best example of accomplishment.

Soon the possibilities of improving dental conditions in childhood through dental practice became evident to the dental educators, and dental students were all required to attend courses in children's dentistry. Didactic instruction was supplemented by clinical practice on children, and more recently technic courses in relation to the morphology of the temporary teeth and operative procedures have been required in the schools. Refresher courses for practising dentists, dealing with preventive dentistry especially for

children, have been set up by dental organizations and departments of health throughout the country.

Dentists in practice began to specialize in children's dentistry. A pedodontic society was organized, later becoming the American Society for the Promotion of Dentistry for Children. It now publishes a periodical.

One dental school offers an optional curriculum with emphasis on the prevention of dental disease. The students registered in this course are not required to complete courses involving the replacement of missing teeth during the last 3 years of the curriculum. By substituting orthodontics for prosthesis, they may qualify for graduation and receive the degree of Doctor of Dental Surgery. The major part of their clinical experience in college and subsequently in practice is with children and young adults.

So much for the history of the development of the educational phase of improving dental conditions. What about the present need for improving dental conditions, or more pointedly speaking, preventing dental disease?

The health education programs conducted by dental hygienists have in some localities proved to be very effective in stimulating interest in taking care of the teeth. But these programs do not cope with the problem of providing service for children with decayed teeth and other dental lesions. Without some sort of educational activity, the effective demand for dental service is very low, for several reasons: ignorance, fear, inconvenience, and costs. But when interest is aroused, service for children should be available.

Fairly reliable estimates indicate that there are about 30,700,000 children aged 2 to 14 years, inclusive, and about 12,000,000 more aged 15 to 19 years, inclusive, in the United States. Most of them are in school or college. This group of 42,700,000 represents

about one-third of our population. All of them need some kind of dental service every year. If each of these children received 4 hours' dental service on an average each year, it would require the services of 89,000 dentists working 40 hours a week for 48 weeks a year to care for them. Each dentist would care for about 500 children a year. There are about 71,000 dentists licensed to practise in the United States, of whom perhaps 65,000 are actively engaged in private practice.

If a program of service for children were put into effect, the adult population would have to be forgotten in so far as dentistry is concerned. Would the older patients yield to the children? I doubt it. And the possibility of securing service for all is not likely to improve, for the number of students attending dental schools is now much smaller than it was 10 years ago, so that as the older practitioners retire there will be fewer young men to replace them.

What about dental equipment? During the last score of years dental manufacturers have devoted their attention to the refinement and embellishment of dental equipment, materially adding to the cost until a single installation may cost from \$2,000 to \$5,000. A recent survey by the New York State Dental Society¹ states that the average cost of equipment is \$5,260.

One health officer I called upon in September, 1937, induced a group of dentists in his community to accept a plan whereby each would render a volunteer service, giving $\frac{1}{2}$ day each week in a central office. The dentists submitted for this a list of equipment and instruments which would cost \$5,000. He had \$600 in reserve to equip the dental office with used furniture and so advised them. Their reply was that they could not work in an office unless the equipment was up to the standard to which they were ac-

customed. The clinic was not started and the health officer was at a loss to understand the situation because he had equipped another clinic a few months earlier for \$450. A young dentist was rendering a satisfactory service there part-time at a moderate salary and at least some of the children were being cared for with mutual satisfaction.

I believe that a durable, comfortable, form-fitting pressed steel chair with a few attachments, such as a head rest, arms, and cuspidor, a pressed steel case for instruments, and a portable electrically driven dental engine could be produced in quantity lots for \$100 a set, allowing a generous margin for profit to the manufacturer and I believe that within a decade 100,000 of such outfits could be placed in cubicles in health centers or in school buildings to facilitate rendering the service the children require. The nurse and physician could find good use for this equipment, too.

All over the country health departments and schools are confronted with the problem of providing some type of dental care for underprivileged children. This, at present, is not accepted as a responsibility by governmental units, because it is looked upon as a phase of medical care; yet in thousands of communities all over the land dental service is being rendered through these channels where the official group is aided financially and socially by such volunteer organizations as Parent-Teachers Associations, Service Clubs, etc. One of the difficulties confronting these groups is the high cost of dental equipment. If the dental manufacturers are not interested in this problem, undoubtedly others will be in the near future.

The last phase of this question on the possibilities and means of improving the dental conditions of children in this country, and which I shall present from the educator's point of view, is the

problem of service. You all know the need for it and realize the inadequacy of what is offered at present, especially in so far as the underprivileged child is concerned.

When in Edinburgh 12 years ago I visited the Queen's Nurses Home, a headquarters office from which a group of noble women are sent to care for the needy in all sections of that city. There, I learned that these nurses were trained during a 2 year course of study to attend the expectant mother during confinement, as well as to give prenatal and postnatal care. By such a procedure the practice of midwifery was gradually being undertaken by qualified, well trained nurses who cared for the poor.

In Maryland in 1937, I learned from Dr. J. Mason Knox that a similar plan had been in effect there for several years, under the jurisdiction of the Division of Maternal and Child Hygiene of the State Department of Health. If the physicians in the locality where a pregnant woman resided declared to the Health Department that they would not confine the patient, then the patient had the choice of a midwife, who must be paid by her, or a public health nurse, whose salary was paid by the state. If the midwife was called, the nurse made it her business to be present to see that the midwife complied with the state regulations governing the procedure at delivery. I believe that you will all agree with me that such an operation is far more serious for the patient than cleaning teeth, filling small cavities, and extracting temporary teeth.

Does it not seem possible to you that we should be able to train persons to do these simple operations for children in 2 years time? One phase of this service is now being rendered by dental hygienists with only 1 year of training in some states and the results have been good. \

If such operators were given 2 years' dental training based on 2 years of pre-dental study, licensed to perform a limited service, and were placed under the supervision of licensed dentists who would counsel and direct them as physicians now counsel public health nurses, would it not be a desirable way of attacking this stupendous problem of dental care for deserving children? Provision could be made in our educational institutions, if they are willing to accept the responsibility, to continue the education of such workers, should they desire it, to the point where they might be awarded dental degrees.

The dental profession probably will not accept this program. Many schools will not endorse it. But in my judgment it is a very logical and economic way of solving the problem of dental care for the underprivileged children in our land. Thousands of young men and women could find employment under such a plan, rendering a needed service to worthy children, earning a compensation equal to that paid to others of like qualifications and skill. And, in due time, the children for whom they care will enter the self-sustaining group in a much healthier state than is the case at present. They will be more appreciative of and presumably better able to pay for their needs, including medical and dental care in later life.

The problem with which we are really concerned is the prevention of dental disease and dento-facial deformities. Health education, adequate nutrition, personal hygiene, eradication of infection, correction of endocrine dysfunction, correction of inherited defects—all contribute to the desired end. Of these I believe that nutrition, personal hygiene, and health education are the most important, for no program in preventive dentistry thus far inaugurated has been successful without these. We cannot, however, rely on any one or all of these to the exclusion of indi-

vidual dental care. This must be recognized as perhaps the major factor for some time to come. Dental attention must be given to the mother during the prenatal period and during the infancy of the child, and to the child itself from 2 to 21 years if we expect to attain our goal.

Why, in the United States where dentistry is universally conceded to be the best in the world, is there no lessening of the prevalence of dental decay, especially among children?

Medical Students

"... They naturally have faith in their instructors, turning to them for truth, and taking what they may choose to give them; babes in knowledge, not yet able to tell the breast from the

bottle, pumping away for the milk of truth at all that offers, were it nothing better than a Professor's shrivelled forefinger."—Oliver Wendell Holmes, *Medical Essays*, 1855.

How To Improve Dental Conditions in the United States*

C. E. TURNER, DR.P.H., SC.D., F.A.P.H.A.

*Department of Biology and Public Health, Massachusetts Institute of
Technology, Cambridge, Mass.*

THIS discussion was organized to consider specific suggestions for improving the dental health of the nation. The writer has three steps to propose.

The first proposal is an appreciable expansion of the present program of public dental health education through the agencies of the dental and public health professions, acting under both governmental and private auspices. There is probably no disagreement as to the desirability of this step. The rank and file of the American people do not yet understand that—with some latitude for individual differences—parents can insure good teeth to their children through the three-point program of adequate nutrition, suitable oral hygiene, and regular dental care.

The organization and methodology of such a program, using visual material, the spoken word, and the written word, is a subject inappropriate for discussion at this meeting. The proposal is for a national dental health education committee, representing all of the interested organized groups. Such a committee would secure agreement upon the fundamental coördination of par-

ticipating agencies and the expansion of a program to the point where increased national attention would be secured.

Second, schools can further improve their teaching of both oral hygiene and nutrition—particularly the latter. A tremendous improvement is possible in securing regular dental attention for pupils.

In Malden, Mass., we have raised the percentage of elementary school children having all necessary dental work completed each year from 30 per cent in 1927, to 71 per cent in 1937, without any increase in the amount of free dental service. This effective health education is developed in coöperation with the local dental profession. The private dentist or clinic dentist signs a certificate for each pupil when all necessary dental work has been completed. Each teacher and her pupils try to get as many members of the class as possible to secure all necessary dental attention before the end of the school year.

This proposal uses health education with home attention and dental coöperation instead of unlimited free dental service. It operates upon the philosophy that regular dental care is desirable and that children should be educated to secure such service upon their own

* Read at a Joint Session of the Child Hygiene and Public Health Education Sections and the Oral Health Group of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 28, 1938.

initiative and at their own expense unless prevented by poverty.

The third proposal is the development and use of standards for measuring the dental health of school children in order that a school or a town can observe its own progress from year to year and compare its dental health status with that of other communities. Possible standards for comparable purposes include:

1. The number of children having all necessary dental work completed during the school year

2. The number of cavities filled per 100 children in the completion of this work (This information can be secured from the dentist if space is provided for it on the dental certificate)

3. The number of lost six-year molars at each age level.

4. The number of perfect six-year molars at each age level

5. The percentage of children at each age having four perfect first molars

You will recall that the American Child Health Association found that the six-year molar serves as a very good index of the dental health of the child population. In a recent study of 600 children in our 6th and 7th grades, we found that 98 per cent of the lost permanent teeth were six-year molars.

Dr. Wisan has proposed a lost permanent tooth index which shows the number of permanent teeth lost or needing extraction per 100 children and the percentage of children who have lost one or more permanent teeth. Our experience in having two dentists examine the same group of 184 7th grade children shows a very wide divergence in judgment as to the number of teeth needing extraction (59 per cent agreement for all permanent teeth and 68 per cent agreement for six-year molars).

It shows a much higher degree of consistency in reports upon the number of lost six-year molars (89 per cent agreement).

One might at first think that the number of cavities and the number of fillings in the six-year molars might provide a good index of dental health and that the ratio between these two figures would reflect the adequacy of the dental service secured by the pupils. The wide disagreement between dentists examining the same children in these respects indicates, however, that these measurements probably cannot be used.

This is not the place to develop a detailed discussion of the possibilities and difficulties encountered in securing a satisfactory index of dental health. It is certain that an objective and accepted index would have tremendous value in motivating the dental health education program in the public schools. It is also probable that a satisfactory index can be found. Rapid progress could be made if such a group as the National Dental Health Education Committee proposed above, or a committee appointed by some suitable professional association or official agency, would undertake to bring together existing information, to carry out such additional studies as may be necessary, and thus to evolve and present an objective standard.

In summary, the writer has proposed: (1) extension of our present public health education program in dental hygiene, (2) extension of the school health education program in dental hygiene with emphasis upon dental attention and coöperation with private dentists, and (3) the development of nationally accepted and objective standards of dental health.

Selection and Training of Dental Health Personnel*

FRANK C. CADY, D.D.S., C.P.H., F.A.P.H.A.

*Dental Consultant to the State Health Authorities,
U. S. Public Health Service, Washington, D. C.*

IN order to provide a background for this discussion of dental health personnel, it will be necessary to review briefly the history of the organization of public dental health services.¹ Twenty-four years ago Dr. Alfred Fones trained some women to clean teeth and later placed ten of them in the Bridgeport, Conn., schools to clean and inspect the teeth of the children and provide a measure of dental health education. Twenty years ago, the State Health Department of North Carolina employed a few dentists to examine and treat the teeth of school children. This was the initiation of dental health service in city and state departments and came fifty years after the formation of the first state health department. From this you will note that with the possible exception of industrial hygiene, dental hygiene is the youngest specialty of public health work.

According to *Public Health Bulletin No. 227*, 14 state departments of health and 2 state departments of education, in 1933, employed personnel to conduct dental programs. This personnel consisted of 60 dentists, 14 hygienists, and 2 teachers. A majority of the dentists

were part-time and all but 8 were occupied with clinical work. All but one of the hygienists were employed full-time and most of their time was spent in cleaning the teeth of school children.

In commenting on the organization of these dental services, *Bulletin No. 227* states that methods of operation varied widely in all 14 units. In most of these departments, the dental activities were carried on as a part of the Division of Maternal and Child Health; a few were separate bureaus directly under the health officer.

The funds made available by the passage of the Social Security Act stimulated tremendously the development of dental health services, particularly in state health departments. By the end of 1937, 33 states had organized dental health units in these departments. Twelve were separate bureaus directly under the state health officer, the remainder were subdivisions of other bureaus—chiefly, the bureau or division of maternal and child health.

In these 33 states, there were 40 dentists devoting their time to administration and organization—an increase of 32 or four times the number in 4 years. There were 94 dentists employed for field work, over half of whom were full-time. There were also 34 full-time hygienists, 6 teachers, and 7 nurses.

* Read at a Joint Session of the Child Hygiene and Public Health Education Sections and the Oral Health Group of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 28, 1938.

Recent surveys in 93 cities of over 100,000 population show a total of 397 full-time and part-time dentists employed by either the health department or public schools; 15 of these devote their time to administration, organization, and education; the remaining 382 are clinicians. Employed also in the health or educational departments of these cities are 172 dental hygienists and 15 nurses—all employed full-time. All together, there were 768 people employed either full-time or part-time in 33 states and 93 cities to promote dental health. This, of course, does not account for the large number of dental personnel employed by counties and cities with less than 100,000 population and by private agencies. Indications are this number will exceed the total in the states and cities surveyed.

While funds provided by the Social Security Act stimulated a rapid increase in dental health personnel, yet the organizations directly affected took little concerted action regarding the type or qualifications of dental personnel until this year.

Any discussion of the qualifications of different types of dental personnel is directly related to broad objectives of the dental health program. There is general agreement that these objectives consist of—(1) the control of dental defects in their incipiency, (2) an educational program to motivate the younger age group to have defects corrected early and periodically, (3) education for the promotion of better nutrition and hygienic habits, (4) provision for the correction of dental defects of those unable to afford it.

A study of the basic professional

TABLE I

Dental Personnel in State and City Health and Education Departments in 33 States and 93 Cities with Over 100,000 Population

Unit	Dentists Adminis- trative and Edu- cational (full-time)	Dentists Adminis- trative and Edu- cational (part-time)	Dentists Clinical (full-time)	Dentists Clinical (part-time)	Hygienists (full-time)	Teachers (full-time)	Nurses (full-time)	Total
33 States	40	3	55	39	34	6	7	184
93 Cities	5	10	144	238	172	..	15	584
Total	45	13	199	277	206	6	22	768

The purpose of presenting these data is to show you the rapidity with which public dental health services have been developed in the last few years and to impress you with the importance of the organization and training problems involved.

An analysis of available data^{2, 3, 4} shows that dentists, dental hygienists, teachers, and nurses have been selected for dental administrative and educational purposes, indicating a difference of opinion among public health officials as to the type of personnel best fitted to direct and promote the dental health program.

training of dentists and dental hygienists will show that they generally are equipped to promote only the clinical aspects of the program. A teacher is trained chiefly in the fundamentals of general education, with only a minimum of training in health education. Public health nursing courses are deficient in training in educational methods and dental hygiene. It is readily understood, therefore, that none of the personnel enumerated is qualified to administer and promote a well rounded dental health program, without additional graduate training and experience.

In addition to a distinct lack of

trained personnel in this field the solution of the problem of selection and retention of competent dental personnel is beset with the same vicissitudes as is the selection and retention of other health personnel. Pressure of political consideration and the demands of the dental associations in particular, have forced some health officers to appoint local personnel when better trained persons were available in other cities and states. Few states have civil service requirements, which is the best method of selection and retention so far devised.

It is recognized that the promotion of the dental health program may require the concerted efforts of the several different types of personnel mentioned. It would seem, however, that the logical person to administer the program in a health department is a dentist with general training in basic public health administration and special training and experience in health education and children's dentistry.

As previously stated, the present-day program is based largely upon the control of dental defects as early in life as possible and as often as necessary. This is to a large degree a professional dental service problem requiring orientation and training of practising dentists and the organization and supervision of adequate clinical facilities for those who cannot afford private service.

The problem of selling and educating the dental profession to provide competent dental treatment for children is one of the most difficult confronting the health department or school. To accomplish this special literature has been prepared, undergraduate schools of dentistry are being stimulated to improve courses in pedodontia, clinical courses and lectures are being promoted at dental meetings, and "refresher" courses for rural dentists are being conducted by health departments.

The rank and file of the dental profession is convinced that a dental pro-

gram, dependent as it is on increased and improved clinical service for children, should be directed by a dentist.⁵ In 1937 the House of Delegates of the American Dental Association passed a resolution requesting that directors of dental bureaus or divisions conducting state programs be licensed dentists. A number of state dental societies have passed similar resolutions.

It is obvious that for the time being, at least, the service side of the dental health program is the predominant one and that a great amount of assistance must come from the dental profession if it is to be successful. This would indicate that a dentist with graduate training in other necessary aspects of the general public health program is the logical person to administer and promote dental health in a health department.

Numerically, at least, the dental hygienist is the next in importance in the dental health field. Of the full-time personnel employed in this work the hygienists exceed in number all other combined. Primarily, the idea of the hygienist was conceived to provide the practising dentist with assistance comparable to that provided by the nurse for the physician. Her training was, and is largely today, pointed toward the cleaning of teeth, care and sterilization of instruments, and assisting the dentist with his operations. Almost from the beginning, however, schools and health departments, state and local, have employed hygienists to assist in the promotion of the dental health program.

There is considerable difference of opinion on the value of the dental hygienist in this field. Some contend there is no place for her in public health work, that the field is already overloaded with specialists, and that other than making individual dental examinations, there is little of value she can contribute that a school teacher, public

health nurse, or public health educator, cannot perform as well with some additional training. However that may be, it is quite obvious the dental hygienist must be trained to provide a service other than cleaning teeth and making dental inspections if she is to survive in public health work. So far, only one school offers a course for dental hygienists that will fit them for a public health career. There are only a few teachers devoting their entire time to dental health education. The few who have had graduate training in biology, physiology, general or dental hygiene, and other kindred subjects, are very helpful in the promotion of dental health education in the schools. Their schooling in the basic educational subjects fits them better than any other type of health personnel to organize and build dental health educational material and programs for school use. The teacher's entree in the schools is comparable to that of the dentist in the dental organizations. When it is understood that the success of the important school dental program is dependent upon the active coöperation and participation of dentists and school teachers, the importance of these individuals is readily understood.

The public health nurse is also a very vital factor in the promotion of a successful dental health service, especially among the important preschool group. The public health nurse is an important link between the home and the school and an important factor in the health program of the adult. Hers is a *personal* contact of recognized value in health education; a guiding hand from pregnancy to maturity. We must depend upon the public health nurse if we ever succeed in sending to school for the first time children free from dental defects. As in other public health fields, the dental health program is handicapped by the scarcity of trained public health nurses.

With some special training, the public health nurse can occupy an important place in the dental health program as a consultant to nurses in schools and in the field, in promoting school and preschool dental service. However, since the trend in public health nursing is toward general and away from specialized nursing, they can and should add dental hygiene to their training program. It is unfortunate that graduate courses in public health nursing have so little in them relating to dental hygiene.

I have enumerated the types of personnel at present employed to promote the dental program in health departments and described briefly the services they perform. I have tried to make it clear that few of them have had the specialized training necessary to fit them to perform these duties with a maximum of efficiency. It is true that by virtue of superior intelligence, hard work, study, and experience, a few have developed into efficient dental health workers. These, however, do not compensate for the large number recently employed who are handicapped in the performance of their duties by lack of adequate training.

The Public Health Service has urged in every instance that newly appointed, untrained dental personnel be sent for training in the fundamental subjects closely allied to their work. For some unknown reason, few health officials have taken advantage of the opportunity provided by the Social Security Act as far as training of dental personnel is concerned. Since the Act became effective, only 4 dentists have completed 8 month courses, 18 dentists were given short courses (16 of these in one state). A few dental hygienists and teachers have taken short summer courses in education to assist in preparing them for this work.

Arbitrarily we might say that any subject matter of a basic public health nature related to the special field of

dental health is essential to the preparation of dental health workers. At the April, 1938, conference of the State and Territorial Health Officers with the Surgeon General of the Public Health Service a schedule of standard qualifications was set up for public health dentists. The following is a summary of the minimum requirements adopted:

I. Basic educational requirements shall be:

- A. The degree of Doctor of Dental Surgery from a reputable dental school
- B. Not less than 3 years of clinical experience in the general practice of dentistry

II. Special qualifications:

- A. For dental officers of health of jurisdictions of less than 150,000, or those in subordinate positions in larger jurisdictions

1. Candidates for appointment shall be not more than 35 years of age. Preference shall be given to candidates in the following order—

- a. Those who have had training and experience in children's dentistry
- b. Those who have had one or more years experience in the general practice of dentistry

2. Personnel selected shall already have had or shall agree to take before assuming duty not less than the first semester course in a recognized school of public health

- B. For dental health officers of jurisdictions having populations of more than 150,000, for staff positions with state health departments, and for positions having the responsibility of supervisory and consultative service—the following standard of qualifications shall apply:

1. Not less than 1 year in residence at a recognized university school of public health and the satisfactory completion of a course of study in the following fundamental subjects in preventive medicine and dentistry: Biostatistics, Epidemiology, Health Administration, Sanitation, Communicable Diseases, Nutrition, Health Education, Dental Health Administration, Oral Manifestations of Communicable Diseases, and Children's Dentistry
2. Six weeks of field experience under proper supervision

III. Exceptions to the foregoing standards for dental officers may be made only when candidates for positions have, through experience and practical training, proved ability to perform successfully the duties of the position for which application is made.

All schools of public health accept dentists as students for both the short and full year courses. Harvard, Columbia, and Michigan, offer a full school year course in public health dentistry in addition to the required courses in fundamental public health subjects. These schools offer courses to dentists in Pedodontia, Oral Pathology and Oral Communicable Diseases, Health Education, and field work in Dental Public Health Practice. To the best of my knowledge, the University of California is the only school that offers a special course to dental hygienists intended to prepare them for public health work.

If teachers, nurses, and dental hygienists, are to be used in subordinate positions in the field, consideration should be given to their basic qualifications. The teacher does better work with the school health educational program; the public health nurse with the maternal, infant and preschool group; and the dental hygienist for dental inspections.

The following qualification standards are suggested to equip the individuals in these categories for field work dental health service:

1. Dental Hygienist—She should have an A.B. or B.S. in Education and have had a minimum of 1 academic year in a *special* oral hygiene course. (Special oral hygiene course, means a course in which a majority of the time now devoted to operative procedures is given over to a study of basic medical and dental subjects and to general hygiene.)

2. Public Health Nurse—A Registered Nurse with a certificate in public health nursing and a minimum of 1 academic year graduate training in health education or in a special oral hygiene course.

3. Teachers—An A.B. or B.S. in Education

and a minimum of one academic year graduate training in health education or special oral hygiene course.

It is hoped that the graduate training schools for nurses and teachers and public health educators will provide courses in dental hygiene. In certain localities, a few dental and public health schools offer graduate and postgraduate courses in subject matter pertinent to dental public health that may be taken by nurses and educators as optional subjects. Whether or not a teacher, public health nurse, or educator, expects to specialize in the dental health field, it is hoped these key people

will be offered courses in dental hygiene and allied subjects to prepare them better to assist in the program to reduce the high prevalence of dental defects.

Immunization Against Tetanus with Alum-Precipitated Tetanus Toxoid

D. H. BERGEY, M.D., D.P.H., F.A.P.H.A.,* CLAUDE P. BROWN, M.D., AND S. ETRIS

Research Laboratories, The National Drug Co., Philadelphia, Pa.

IN the earlier papers by Bergey and Etris in 1933^{1,2} on the immunizing value of tetanus toxoid it was shown that the plain toxoid or anatoxin of Ramon³ was much too irritating for human use. Therefore they refined the plain toxoid by precipitating it with aluminum potassium sulphate and washing, a method similar to that of Wells, Graham, and Havens⁴ for diphtheria toxoid. They found that the resulting alum-precipitated toxoid stimulated the formation of tetanus antitoxin when injected into guinea pigs. The alum-precipitated toxoid used throughout these experiments was prepared from a toxin which contained 10,000 m.l.d. per cc. before detoxification.

Preliminary work was done by injecting guinea pigs at various intervals with 1 cc. doses of alum-precipitated toxoid. It was found that the serum of such guinea pigs receiving two injections given 90 days apart contained as much as 20 units of tetanus antitoxin per cc. Comparative tests made at the same time demonstrated the superior antigenic value of the alum-precipitated toxoid over the plain toxoid. The results of these experiments led to the following studies made on two groups of humans, youths and adults.

Thirty persons, between 18 and 20 years of age, volunteered for the first studies. Bleedings were taken before treatment and the serum tested for the presence of antitoxin[†]; however, none was demonstrated except traces possible within the limits of experimental error. An injection of 1 cc. of alum-precipitated tetanus toxoid was given and bleedings were taken 25 and 90 days later. The results showed that tetanus antitoxin is produced slowly after the first injection, reaching the maximum amount, 0.001 to 0.04 unit, in the 90 day period. The second injection was given 90 days after the first injection and tests after 30 days showed there was an increase of the antitoxin,⁵ from 0.1 to 9.0 units of antitoxin per cc. of serum. The first injection (primary stimulus), as shown in animals, seems to prepare the antibody-forming cells, so that subsequent injections are followed by a marked increase in the quantity of antitoxin in the blood.

In August, 1935, an older group of 44 individuals between 30 and 50 years of age was selected for study. The preliminary bleedings showed an absence of

[†] We wish to express our appreciation and thanks to Russell Knerr and George Hottle of the Swiftwater Laboratories for their assistance, which involved a large amount of work, in testing the sera for antitoxin values. Their method of testing for small amounts of antitoxin was published in *J. Infect. Dis.*, 55:360-362, 1934. We are also greatly indebted to Dr. W. B. Rawlings for the toxin used in these studies.

* Died September 5, 1937 (see *A.J.P.H.*, Dec., 1937, p. 1205).

antitoxin. Each member of the group was given 1 cc. of alum-precipitated toxoid and no local or systemic reactions occurred. A bleeding was taken 90 days later and the antitoxic value of the serum determined. The antitoxin ranged from 0.0005 unit to 0.01 unit per cc. of serum. Approximately 50 per cent of the individuals showed 0.0005–0.0008 unit of antitoxin. Three showed 0.01 and 23 showed 0.001–0.005 unit of antitoxin in 1 cc. of serum.

The amount of antitoxin contained in the serum after the first injection of toxoid is, however, no indication of the possible stimulation given by an additional injection of toxoid. A second injection of 1 cc. of alum-precipitated tetanus toxoid was given 90 days after the first injection, and a bleeding taken 105 days later, or an interval of $3\frac{1}{2}$ months after the second injection. The antitoxin content of the serum had increased 100 to 500 times its previous value and, with the exception of three sera which tested 0.03 unit, all contained 0.01–0.4 unit of antitoxin per cc. of serum.

A comparison of the results obtained by immunization of this older group from bleedings taken $3\frac{1}{2}$ months after the second injection, and those from bleedings of the younger group one year after the second injection, showed that the older group contained less antitoxin. In the lower age group not one serum showed less than 0.001 unit of antitoxin 90 days after the first injection, while about 50 per cent of the older group showed about 0.0005 unit.

Nineteen months after the second injection a second bleeding of the older group was taken and the serum tested as before. The antitoxin had decreased to approximately one-fifth of the former value and the serum of 14 of the 44 individuals now contained less than 0.01 unit of antitoxin. This amount is thought to be too low to

prevent the development of tetanus and such persons should have their immunity increased by giving an additional dose of toxoid.

There is difference of opinion as to the amount of antitoxin necessary to protect man from the development of clinical tetanus.

Sneath⁶ states "Of 29 persons given three doses of tetanus toxoid, significant amounts of antitoxin developed in 28, a titer of at least 0.1 unit per cubic centimeter of serum being reached in the majority, or 20. From 5 to 7 months after the last dose there was in general a reduction in the antitoxin level, but 27 still showed demonstrable antitoxin, the majority, 25, showing 0.01 unit or more."

Sneath⁷ also states: "In order to obtain an estimate of the relative protection afforded man by such levels of antitoxin, the blood antitoxin of 9 individuals, following the administration of the usual prophylactic dose of antitoxin (1,500 American units) was determined. Approximately 72 hours after intramuscular administration, the level was 0.1 or $> 0.1 < 0.25$."

Sacquepée⁸ states that from 0.1–0.2 unit of antitoxin per cc. of serum would probably be sufficient to give a considerable degree of immunity when one takes into consideration the sensitizing effect upon the cells concerned in the production of antitoxin.

From our own observations on the immunizing effect of toxoid we arbitrarily chose 0.01 unit of antitoxin per cc. of serum as the minimum protective level. In persons previously injected with multiple doses of toxoid, this amount of antitoxin can, in case of injury, be increased rapidly by giving an additional injection of tetanus toxoid.

Laboratory experiments have shown that the circulating antitoxin, as estimated by the mouse-protection test, does not represent the total protection. Immunized guinea pigs, showing 0.2

unit of antitoxin per cc. of serum, computed in terms of total humoral protection, will neutralize 6,000 m.l.d. of tetanus toxin. However, these pigs will tolerate an injection of 15,000 m.l.d. of tetanus toxin without showing any evidence of tetanus intoxication.

If we accept the difference between humoral protection and total protection as non-circulating or so-called cellular immunity, then the non-circulating immunity, at least in guinea pigs, is $1\frac{1}{2}$ times greater than the humoral protection which can be estimated by testing the blood after immunization.

Experiments by Rawlings⁹ have shown that guinea pigs immunized with 1 cc. of refined tetanus toxoid will tolerate injections of tetanus spores. Six weeks after the immunizing dose each pig was given a large dose of tetanus spores. The spore emulsion was prepared from an old agar culture which had been heated at 85° C. for 20 minutes to destroy bacillary forms and any existing toxin. Two grains of quinine sulphate was added to each dose as a necrotizing agent. The immunized pigs were all protected while the control pigs died within 5 to 9 days.

CONCLUSION

A comparison of the amounts of tetanus antitoxin found in persons of different age groups with refined tetanus

toxoid has shown that 90 days after the first injection the blood serum of older persons does not contain as much antitoxin as persons in the lower age group.

The second injection greatly stimulated the formation of antitoxin in both age groups but the average antitoxin titer was somewhat higher in the lower age group, and there also appears to be a greater loss of antitoxin from the blood stream in the older age group.

This investigation suggests that in immunizing older persons with tetanus toxoid it probably is necessary to give more than two doses of toxoid to develop a basic immunity.

Studies on the immunization of persons against tetanus are being continued with a refined toxoid prepared from a toxin having an original titer of 100,000 m.l.d. per cc.

Essential Problems in Pertussis*

HAVEN EMERSON, M.D., F.A.P.H.A.

Executive Officer, DeLamar Institute of Public Health, College of Physicians and Surgeons, Columbia University, New York, N. Y.

IF epidemiology is the servant of the health officer as well as a form of intellectual discipline and a field of science devoted to unravelling some of the phenomena of disease, we can properly review the present status of our knowledge or ignorance about pertussis to make sure that we are using our opportunities effectively to add to our facts and for the reduction of its incidence and death.

The fall in the reported death rate per 100,000 of total population, and in the case fatality per cent for pertussis in the past two decades in representative cities of the United States has been considerable:

DEATH AND CASE FATALITY RATES FROM
PERTUSSIS IN 32 CITIES OF THE
UNITED STATES *

	Average Death Rate per 100,000	Case Fatality Per cent
1924-1928	5.22	3.13
1929-1933	2.00	1.09

* Population at all ages in these cities was 21,904,758 in 1924, and 26,219,638 in 1933. The deaths numbered 5,820 in the first quinquennium and 2,469 in the second. The cases reported in the first quinquennium numbered 185,699 and in the second 224,606.

These apparent improvements in the situation seem to me to have been related more closely and consistently to a falling birth rate, and the resultant

effects on age grouping of the population, and upon the size of families, and upon the age at which the children are exposed to the disease, than to any specific factor in the private or public practice of medicine such as active or passive immunization of susceptibles, better treatment of the sick, or more effective isolation and other administrative measures directed toward the control of pertussis.

It would seem reasonable to expect that the case fatality of pertussis might have been favorably affected by the better home hygiene, antirachitic and other nutritional advances in the dietaries of children, more general and skilled home nursing of patients during isolation, and other factors which we see applied for the benefit of children under 5 years of age, but there are, I believe, no studies to confirm these general impressions.

ADMINISTRATIVE PRACTICES

If one were to note the features of current common administrative health practices which in some way hinder us from a more exact analysis of the downward trend of pertussis, one would note first that few if any health departments tabulate, if indeed they require the initial report card to include a record of, the age of the patient. Thus in attempting to study the trends in incidence and fatality rates which calls at least for age specific tabulations

* Read at a Joint Session of the Laboratory and Epidemiology Sections of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 25, 1938.

by years up to 5, and by 5 year groups up to 15 years of age, one finds practically no published data except perhaps from Providence, R. I., and in fact no records on file in health departments of cities from which case and death rates by necessary age groups can be calculated.

Second, one finds a very considerable incompleteness of reporting, the extent of which varies widely according to the interest and adequacy of the local health and medical services of the community, from approximate completeness to about 5 per cent of estimated cases.

Third, one finds that routine departmental procedure in establishing the diagnosis and recording the presumed susceptibility, exposure, and subsequent history of infection in households where other children than the reported patient are living, is neither uniform nor adequate to permit study of the relative merits of isolation periods of different lengths, of inoculations intended to prevent, or of therapy designed to modify the course of the disease.

It is the lack, it seems to me, of reasonably adequate, uniform, and effective recording and follow-up practices by health departments which has made it necessary to set up elaborate and very costly studies to learn whether what we are actually doing has any appreciable influence on incidence and deaths, and whether any immunizing procedures proposed by public authority or introduced in private practice by commercial promotion have any promise of good results.

The Sub-Committee on Whooping Cough of the Committee on Evaluation of Administrative Practices at its meeting last October made the following statement, and members of that sub-committee will give us some results of their studies since then.

The special study committee on whooping cough feels that there is a need for further

carefully collected data regarding the epidemiology of whooping cough, particularly the problems of early diagnosis and the recognition of mild and abortive cases, and would welcome information concerning such studies which are now under way or which are contemplated in the future.

The work planned by the special study committee on whooping cough for the ensuing year may be tabulated briefly as follows:

1. An analysis of Dr. Kendrick's immunization studies
2. A critical survey of the literature on the prophylactic use of whooping cough vaccine
3. An attempted evaluation of the pertussis immunization studies now in progress in the United States and Canada
4. A close coöperation with the committee on laboratory procedures in (a) a study of whooping cough antigens, and (b) an attempt to find methods which might, in part, be substituted for the present time consuming methods of testing the efficacy of pertussis vaccine as a prophylactic agent

This is not the occasion nor this audience the one for which warning of the severity of the disease, its direct and indirect damage to health, growth, resistance, particularly of young children, would be appropriate. We are aware of the leading rôle of pertussis among the acute communicable diseases of early childhood. What we know that will help us to control it can be briefly told, and what we must still search for and prove of greater worth is an open field for study.

The etiologic agent we know, also its source in the sick person, and how it is transmitted. The period of incubation is known with more certainty than the period of communicability, and yet the latter is fairly uniform and calculable. We assume, though without precise proof, that all persons are susceptible until they have had the disease, unless there be a spontaneous reduction in susceptibility with age after 15 years, and that active immunity of lifelong duration usually follows recovery from a clinically recognized attack. Several administrative procedures are in the stage of acute discussion, one, the use of plate cultures to establish or confirm

diagnosis, and to determine the end of the period of communicability; another, the use of vaccines for the prevention and treatment of pertussis; a third, the use of convalescent serum for passive protection of exposed young susceptibles and modification of the severity of an attack. It would be of great value if we had a specific test for immunity or susceptibility.

With regard to the use of the plate culture method, its usefulness and practicability as a public health laboratory procedure to aid diagnosis and to determine the end of the period of communicability, have been extensively tested in Denmark with satisfactory results. It has been used in a few cities in the United States but not as a routine, for any considerable period of time nor with practical results of any particular value. Its usefulness has been reported from San Francisco. The Danish and Harvard Whooping Cough Commissions found it reliable in skilled hands. It has not been recommended as a diagnostic test for routine field work by any representative public health organization in this country. It would seem that clinical criteria and white cell counts suffice for diagnosis without verification by plate culture, and that its routine use is too cumbersome and expensive to be justified as a basis for release of the patient from isolation.

Conflicting if not actually contradictory results of carefully controlled use of pertussis vaccines have been common. There are apparently factors related to preparation of the vaccine, to the size and number of doses, to the age and exposure environment of the children, and possibly to the type of the disease in the community or its prevalence during the period of test, any one of which may prove to be significant in the apparent success or failure of its use. There have been enough suggestive results in the hands of quali-

fied observers to encourage further experimental use under a variety of urban and rural conditions, and with vaccines or other possibly immunizing substances of different origins, and over a considerable period of time and number of susceptible children, to answer the uncertainties and inconsistencies of evidence received to date.

The use of convalescent serum and whole parental or convalescent blood has been limited to a few observers. Neither the extent of the use of these substances intended to create passive and temporary immunity, nor the reports of results, have been sufficient to justify recommendation of large scale or routine use of these agents to protect exposed susceptible children under the age of 5 years.

As to a promising test to determine presence or absence of natural or acquired immunity, it can be said that there is none.

If and when we have such a test of susceptibility for pertussis as we have for diphtheria, and if some of the active immunization procedures now undergoing thorough testing prove to be of substantial value we can look forward to their widespread encouragement and possibly their inclusion among the recommended procedures in local health practice.

In the meantime any health officer with even a modest administrative machinery can without any material addition to his record system cull valuable data as to any trends that may develop in different child age groups in regard to incidence, death, and case fatality rates. Also he can inform himself as to the probable extent of incompleteness in the reporting of pertussis by the practising physicians of his community.

I wish to add to my summary two paragraphs from the report of a symposium on pertussis held in San Francisco under the auspices of the Ameri-

can Academy of Pediatrics which I quote from the article by Professor Harold K. Faber.¹

There are, I believe, certain features of these institutional reports which offer clues to the solution of the problem under discussion today. First, it is obvious that the immunity supplied by prophylactic injection of *Hemophilus pertussis* vaccine is not, and cannot be expected to be, absolute. Second, contrary to earlier belief, the immunity derived from a previous attack of the disease itself is also far from absolute. Third, in both cases it tends to break down when exposure is intimate and prolonged. Fourth, under less drastic conditions of exposure both the artificially and the naturally induced immunity appear to afford protection in a large proportion of cases, and in general the protection from both sources appears to be approximately equal. Fifth, there is evidence of partial protection when the immunized individual does acquire the disease, as shown by briefer and milder symptoms.

It is clear, I think, from the evidence that I have reviewed that many problems need

further study. We need more field studies. We need a practical clinical test for immunity. Dosage may need revision, perhaps upward. The optimum intervals between injections may be greater than one week. We do not as yet know how long immunity lasts or the rate at which it declines. There may be strains of *Hemophilus pertussis*, such as the one which Bradford has recently noted, in about 5 per cent of cases, which should be included in the vaccine in order to increase the number of protected individuals.

The above appear to me to be at present the essential problems in pertussis, and with this introduction we can listen to the original contributions of the others on this program who are in the best position to answer some at least of the questions uppermost in our minds, such as those of Dr. J. J. Miller, Jr.

The Exhibit Medium*

HOMER N. CALVER, F.A.P.H.A.

Secretary, American Museum of Health, and Director, Health Exhibits, New York World's Fair, 1939, New York, N. Y.

MAN is constantly trying to break down the barrier which separates him from his fellows by endeavoring to improve his means of communication with them. None of the means so far devised is perfect. The first pictographs were an attempt to supplement the grunts and gestures which must have chiefly served primitive man to convey his simple ideas of food, shelter, mating, and combat with which his life was chiefly concerned. As life became more complex, so the auditory and visual symbols of expression assumed greater exactness, richness, and complexity. As a result the problem for the health educator today is to find a way to break through this welter of words written and spoken, pictures still and moving in black and white and color, fortified for their dissemination by powerful broadcasting stations, national hookups, Kleig lights, million-dollar stars, double features, and block bookings, not to mention high speed presses and mass circulation.

Although these media are also available to us to some extent the exhibit medium offers an effective and under certain circumstances a preferable method, for health education.

THE LANGUAGE OF EXHIBITS

Exhibits may be compared to language. Things exhibited are nouns.

* Read before the Public Health Education Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 25, 1938.

Color is an adjective; motion, the verb. Just as the selection and arrangement of our parts of speech determine the sureness with which we transmit an idea, so the selection and arrangement of our exhibit elements will determine the clarity and dramatic emphasis with which we tell our story through that medium. If I say to you the word "boy" this creates an image in your mind. If I say "black boy" the image takes on character. When I say "fat black boy" the image becomes still more specific. If this image is now put into motion with the words "fat black boy running" it becomes more interesting. So one adds adjectives, verbs, adverbs, and other words and phrases to the single concept "boy" to create a specific picture or arouse an emotion. Within certain limits this picture or emotion will be uniform for the whole audience. So, as one achieves lucidity and force of expression in language through adherence to the rules of composition one achieves similar results in exhibits through adherence to the rules of exhibit technic.

Our knowledge of these rules is still rudimentary, nevertheless there are some general principles which it is important to have in mind. First, it must be accepted that the exhibit medium in spite of its many values has certain distinct limitations. The exhibit as we know it today is not usually adapted to telling a comprehensive and detailed story. It can.

however, point out and drive home a few salient facts. In any one exhibit these facts should be limited in number and be related, because unity is a principle to be followed in any method of idea communication. The excellence of an exhibit is frequently determined by what is left out rather than by what goes into it. Exhibits also can well make use of the teaching principle of proceeding from the known to the unknown. Similarly simple ideas will be grasped more clearly by more people than complex ideas will be. In this connection it is well to remember that an idea which seems simple to the expert may be incomprehensible to the average man. Such an idea for instance as an adjusted death rate though elementary to the vital statistician is not understood by the layman or for that matter by many health workers or physicians. One of the first steps therefore in planning an exhibit is to form a clear concept of the audience to be reached. Many a candidate has lost the farmers vote because he talked in language which only the city bred could understand. It is obviously more difficult to make an exhibit for a group which is diverse as to education, culture, occupation, and age level than it is to make one for a homogeneous group such as a class of farm-bred school children. It should be noted, however, that the exhibit may by its manner of presentation automatically select from a miscellaneous audience the particular group it is desired to impress.

Having the group clearly in mind, the next step is to be sure one is certain of the purpose of the exhibit. Too often exhibits occur merely because some energetic soul has said, "Let's have an exhibit." When an audience is to be assembled as for instance in a convention, county fair, or town meeting, and it is desired to implant in the minds of that audience a few simple

ideas, then one should consider the exhibit as a most useful tool. Only under unusual circumstances such as a World's Fair should one depend on assembling an audience for the single purpose of looking at an exhibit, or attempt to use the exhibit as the sole instrument of education, particularly where the message is of necessity complicated or lengthy. Being aware then of the occasion and circumstances of the showing and having in mind the audience to be reached, the next step is to put down on paper for your own guidance and the guidance of those with whom you will collaborate, the purpose of the exhibit. For instance, "The purpose of this exhibit is to convince my Board of Directors, particularly that skeptical and wealthy Mrs. Jones, that we are spending our present budget very economically and that we should have twice as much money next year to meet our responsibility"; or "The purpose of this exhibit is to induce the farm mothers to bring their babies into town for the free clinic on Thursday mornings."

Setting down the purpose in black and white aids immeasurably in selecting the facts for presentation. Taking the last statement as an example, these facts might be:

1. The clinic is held in the basement of the Court House Annex. (There is no need to tell them in the exhibit how to get there or where to park their cars.)
2. The clinic is held every Thursday morning. (No need to say why it has to be held on Thursday mornings or that next spring it may be changed to Wednesday afternoons.)
3. That services are free and confidential.
4. That a regular check-up of a healthy baby may save expensive doctor bills (or some other one argument that has proved to be most generally appealing).

So far the task seems obvious. It is so logical in fact that I would not have dwelt on it except that I have noticed during an intensive experience with several hundred people who were connected with exhibit planning that

the usual tendency is to begin the other way around. Even before the story or purpose of the exhibit is decided on there seems to be an irresistible temptation to proceed at once to elaborate on or adapt this or that device or attention-getting gadget that has been observed somewhere else. This procedure is like writing the prescription before the diagnosis is made. It is comparable to taking a pill for a stomach ache without finding out what causes the stomach ache. One should guard against this patent medicine method of exhibit planning. Not until purpose and story have been determined is it time to design the exhibit. At this point it is desirable to seek help, employing an exhibit designer if possible. For a large exhibit such design service is essential if funds are to be spent most economically.

It is to be remembered that the exhibit is a distinct medium for the communication of ideas. It may draw on other media such as language and pictures, but if one depends on these aids chiefly it is a confession of failure. An exhibit is not merely an opportunity to show motion pictures or lantern slides to an audience which is standing up instead of sitting down. Though it may utilize charts and text it is not a magnified vertical textbook. An exhibit to be effective must have its own interest qualities, of design, color, movement, or a sense of motion. Among these, design is the most important. Design is to exhibits what rhetoric is to language. The problem of design covers the whole subject of the selection and arrangement of exhibit elements. In exhibit planning, design is unimportant as an end in itself. Design must be related to purpose. The selection and arrangement therefore of color, words, lettering, pictures, devices, light, and other elements should be determined by their relationship to the message of the exhibit and their value in achieving its purpose.

USE OF COLOR

Color is an inexpensive method of achieving effect. It can be secured by paint, ink, cloth, paper, or light. Color should be chosen for its psychological effect, not because someone thinks a certain color is pretty. Color can be used to produce contrast, harmony, emphasis, feeling, and a sense of motion. Juxtaposition of colors can produce striking results. There are few communities in which the health educator cannot find an artist or someone else trained in the use of color, who will be willing to advise him on this point. The local library can usually furnish a book or two on the subject. Among others, *The Study of Color* and *The Art of Color* by Michel Jacobs may be helpful.*

USE OF MOTION

Twenty-five years ago or more, our field was pleasantly stirred by Dr. C. St. Clair Drake, who as far as I know was the first person to introduce motion into health exhibits in this country. About the same time Dr. W. W. Peter employed moving health exhibits as well as many other ingenious devices in his mass health education program in China. The effect of this novelty on a hitherto motionless exhibit world was so startling that we still make a fetish of motion. Dr. Drake in fact maintained that motion was essential to attract attention even if it was nothing more than a flag fluttering in the breeze of an electric fan. Mr. Routzahn has since emphasized however that motion *per se* is not a criterion of effectiveness. He states that the motion must be related to the message. This is in accord with the principles of good functional design. Frequently design can impart a sense of motion and sometimes satisfactory results can be ob-

* Also *The Colorist*, by J. Arthur Hatt, and *Color Dimension*, by Faber Birren.

tained by merely suggesting impending motion such as a sledge hammer about to strike an egg.

LIGHT

Every exhibit should be clearly illuminated, and this nearly always means special lighting for the exhibit. In very few locations can one depend on daylight or the ordinary room lighting. Shadows should be avoided unless, of course, they are deliberately included for effect. Material with a shiny surface should not be used as the background of an exhibit since it produces glare and confusing reflections. Emphasis on a particular point in an exhibit can be secured with a spotlight. Silhouette lighting is very effective. In this method an exact silhouette, in reduced scale of the object to be illuminated, is placed in front of the spotlight so that the edges of the light coincide exactly with the edges of the figure or object. Flashing lights should be used with restraint. These as well as moving devices and other embellishments must not be so "clever" that the visitor is intrigued with their cleverness rather than the message of the exhibit itself.

LETTERING AND TEXT

The rules for lettering and text on exhibits are few and definite.

They are:

1. Keep the amount of text to a minimum. If the exhibit can tell its story with no text at all so much the better.
2. Use short words that everybody understands.
3. Use short lines with not more than 6 or 7 words to a line at most.
4. In a running text use upper and lower case letters. Words with all capitals should be used only for short titles or as an element in design.
5. Text should be large enough to be easily read at the distance from which the visitor is expected to view the exhibit.
6. Use plain Caslon or Futura letters for the message you want to convey. Gothic, Old English, script and other unusual type faces

can be used as an element in design or to produce a desired atmosphere.

VISITOR PARTICIPATION

Just as motion in exhibits has been emphasized in the past, so now the value of visitor participation in animating exhibits is stressed. I believe there is some psychological justification for emphasizing the value of such participation. Sometimes also it is cheaper to arrange for the visitor to animate the exhibit than to equip it with a motor. Common errors in the use of such devices are, however,

1. It is not clear to the visitor what he is supposed to do.
2. The machine is not designed to withstand a heavy visitor load or to prevent deliberate or unconscious abuse.
3. The visitor's interest is so centered on what he is doing that he fails to see or remember the rest of the exhibit.

As was noted under motion, the animation created by the visitor should implement the story which is being told.

TEN TYPICAL DEVICES

The most effective exhibit is one which is properly designed for its specific setting and purpose. There are, nevertheless, many stock devices some of which may be usefully incorporated under certain circumstances. Although some of these now seem trite from repeated use, they are still effective if skillfully employed. Here is a list of 10 such stock devices.

1. *The question and answer device*—This has been extensively used by the American Medical Association in many different forms. It is most useful where there are no other exhibits insistently demanding attention or when the visitor is not hurried.
2. *Moving lights*—These may take the form of a spot of light travelling a prescribed course, a line of light bulbs flashing, or a band of light growing longer and longer. This device is useful to show a route travelled, such as that of a train across the country, or a blood corpuscle through the body, or to carry the visitor's attention from one point of the exhibit to another.

3. *The pendulum*, of which the balance and the swinging pointer are variations—This device can show relationship, comparison or relative values.

4. *Big book with turning pages*—This has been popular with exhibitors but is not always popular with the audiences. Most people would rather read a book sitting down and turn the pages for themselves when they are ready.

5. *Moving signs*—Useful when the location is such that the audience is likely to remain to look at them as in a railroad station. Often, however, moving signs are resorted to simply because the exhibitor is unwilling to reduce text matter and make desirable curtailments in the story.

6. *The Peep Show*—A box or other device into which only one person can look at a time. This is nearly always a sure-fire attraction and may be inexpensive. It is essential that the visitor be given something really interesting to look at and that he be not fooled lest the usefulness of the device be ruined for everyone.

7. *The diorama*—A good old standby since The Century of Progress, getting so common now that it is no longer effective unless very well made, well lighted and represents a scene which is interesting in itself particularly when in competition with other dioramas.

8. *The short motion picture or "quickie"*—Best used when visitor-operated and lasting not more than 30 seconds. Useful to highlight a process or incident. Pictures must have action and good photography.

9. *Enlargement*—A giant typewriter, adding machine, safety pin, flower, or blood corpuscle will attract attention—useful in emphasizing size, number and importance.

10. *Photo montage*—A collection of photographs usually highly enlarged, cut out and fitted together. Pictures must be selected with care, and fitted together with a skill which makes them seem to be assembled without plan. Useful in giving a feeling or general impression as for example, the moving photo montage used to introduce one of the popular news reels.

There are many other stock devices and anyone who is responsible for exhibit planning will find it useful to keep notes of those he sees together with his observations of their value in presenting different ideas.

Finally, it should be emphasized that the setting or surroundings of the exhibit are as important as the exhibit itself. If we have to use a room with windows,

this can be overcome by building a false wall extending from 1 or 2 feet above the floor to within 2 to 3 feet of the ceiling, thus giving an unbroken surface and cutting off confusing cross-lights. Rooms that present a discouraging vista can be broken up with screens. The distracting background of a gold filagree decoration or a wallpaper of intricate pattern can be blotted out with cloth or paper hangings. In general, everything possible should be done to avoid visual conflict between the exhibit and its surroundings, and visual conflict between different exhibits.

In conclusion, let me recommend that you try out your exhibit on a test audience before you present it to the public, and do this if possible before it is too late to make changes. Many of us are so engrossed in the subject matter of the exhibit that we fail to realize that signs, symbols, and words may have a different meaning and implication for us from what they have for the audience. Dr. Gebhard, who has had much experience in the field of medical exhibits, gives me the German word "trugschluss," which as near as I can translate it means false impression or misleading conclusion. After all our efforts we must be sure that our exhibit does not convey some other idea than the one we intended. For instance, at the Museum of Natural History in New York there is an exhibit which aims to show the value of inoculation against typhoid fever. The model represents soldiers in the Spanish American War which occurred before soldiers were inoculated. It shows that out of every 100 soldiers 14 were afflicted with typhoid for every one injured by gunfire. The reaction of an intelligent man who saw this exhibit recently was, "What safe wars they used to have."

In summary then I would list these points for the guidance of health educators who are creating exhibits:

1. Have your audience clearly in mind.
2. Set down the purpose of the exhibit.
3. Select a minimum number of salient points to be presented.
4. Make a design with whatever help you can secure.
5. Incorporate such exhibit technics as you may have observed to be effective and which lend themselves to the telling of *your* story.
6. Incorporate motion or visitor participation if circumstances warrant, funds permit, and these clearly pertain to your message.

7. Tell your story in terms your audience cannot misunderstand, but do not talk down to your audience.

8. Test your plan before presenting it.

9. Experiment a little, judging results by visitor reaction rather than by subjective satisfaction.

Epidemiology of Leptospirosis*

K. F. MEYER, M.D., Ph.D., F.A.P.H.A., B. STEWART-ANDERSON, AND B. EDDIE

The George Williams Hooper Foundation, University of California, San Francisco, Calif.

DURING the past 2 years the Epidemiological Intelligence Services of the West have repeatedly requested coöperation in the solution of the etiologic factors responsible for outbreaks or sporadic cases of jaundice. Epidemics involving small rural schools have occurred in May and June and affected as many as 42 children at one time. In another, the cases of catarrhal jaundice were seen in familial distribution shortly before or during the rainy season which was followed by floods.

Invariably, the serological examination, inoculations of guinea pigs, and the examination of rodents collected within the epidemic area yielded no evidence which would stigmatize the *Leptospira icterohaemorrhagiae* as the causative factor. In fact, a careful analysis of the clinical cases, the incubation time of from 3 to 4 weeks, and the obvious contagious character lead to the conclusion that these outbreaks were indistinguishable from the well known epidemic catarrhal or infective hepatic jaundice previously described by Blumer¹ and others for this country and well known in Great Britain through the publications by Pickles,²

Morgan and Brown,³ Findlay, Dunlop, and Brown,⁴ and in Syria by Yenikomshian and Dennis.⁵

Thus far, all experiments to reproduce this disease in a great variety of animals have furnished little tangible evidence concerning the etiologic agent. An ultramicroscopic agent transmissible to man only is suspected. Sporadic, abortive or latent cases may be the sources of the infection. On the other hand, it must be recognized that single cases of febrile jaundice may be typical cases of Weil's disease. Relatively little attention has been paid to these infections in the United States; in 1937, Packchanian⁶ places on record about 32 proved cases. More recently, 2 sporadic cases have been diagnosed in Rochester, N. Y.,⁷ several in Detroit, and at least 5 have been studied in San Francisco and vicinity. Examinations of serum specimens and sections of organs derived from guinea pigs injected with urine of patients have proved the existence of Weil's disease in the Hawaiian Islands.⁸ There is every reason to believe that these figures merely represent a small fraction of the actual cases.

Experience both in England, particularly London, and in Holland has shown that the incidence in proved diagnosis rapidly increases, provided reliable diagnostic methods are available. Thus,

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 25, 1938.

previous to 1933, less than 4 cases of Weil's disease were reported in London for an entire year. With facilities to test the sera of suspected cases at the disposal of the physicians, the same number of infections are now seen within a month. Since the first case of Weil's disease was diagnosed in 1924 in the Netherlands with the help of a bacteriological examination, not less than 756 cases had been detected by the end of 1936. In Rotterdam, the rate was 56 cases per 400,000 population. Likewise in France between 1924 and 1932, 263 cases were entered in the official records.

Furthermore, it is now recognized that only two-thirds of the patients infected with the leptospira show an icterus. The symptom of jaundice arouses suspicion to such an extent that an examination for leptospira is usually indicated. The relative ease with which a few of these infections have been recognized in California as soon as proper diagnostic methods were available encourages the belief that human leptospirosis may be masquerading under a diversity of diagnoses.

LABORATORY AIDS

The methods of bacteriological diagnosis are delicate and require considerable experience. It is well to remember that the parasites can be detected only in blood plasma specimens concentrated by centrifugation during the first 4 days of illness. Darkfield examinations are very misleading and have not infrequently tempted the examiners to make erroneous diagnoses. The inoculation of guinea pigs with the patients' blood again proves successful only during the early days of the illness, rarely after the 8th day. The animal test is not dependable since certain leptospira strains have a low pathogenicity even for very young guinea pigs. Perhaps, the use of deer-mice (*Peromyscus*) as suggested by

Packchanian or the Richardson squirrels as recommended by Syverton, Stiles, and Berry⁹ may improve the diagnostic yield. These procedures may be supplemented by cultures of the blood but they presuppose a close coöperation between the physician and the laboratory. Experience has shown that the serological tests—agglutination and lysis—followed by animal inoculations with urine or spinal fluid are the most dependable tools in epidemiological work.

The serologic technic developed by Schüffner¹⁰ using living and formalinized (pure formalin) antigens prepared from leptospira cultures in Verwoort media has proved highly satisfactory. With this procedure, the diagnosis of Weil's disease is greatly simplified provided several strains of leptospira are used as antigens, and that titers under 1:300 are not accepted as diagnostically decisive. Esseveld,¹¹ in a careful study on a large series of cases (87), stresses the fact that any titer above 1:300 usually > than 1:10,000 may be safely interpreted as undeniable proof of Weil's disease. In view of the difficulties inherent to these serological tests, it is advisable to centralize the examinations in state or research laboratories with trained personnel.

EPIDEMIOLOGIC OBSERVATIONS IN CALIFORNIA

Since 1927, at least 5 laborers connected with the cleaning and the maintenance of the sewers in San Francisco developed a febrile jaundice resembling Weil's disease. A definite serological diagnosis was made on one case in 1936 and on another in 1937. During the same year, a fatal Weil infection was recognized in a 61 year old Japanese who had worked in his rat infested garden, and an anamnestic diagnosis was made in a veterinarian who serves at the hospital of the Society for the Prevention of Cruelty to Animals and

handles a great many jaundiced dogs. In July, 1938, a filling station operator, aged 27, developed Weil's disease following a fishing trip along the Napa River. He also waded in the mud beds along the wharves and had eaten his lunch in the same area. At the same time, a 28 year old assistant to a veterinarian at Stockton, Calif., with an influenza-like febrile disease was diagnosed as an interesting case of Weil's disease due to *Leptospira canicola*. Investigation of this limited number of human leptospirosis disclosed the existence of two different sources of infection. Nine of the 11 cases had in one way or another been in contact¹ with water or sewage, while two were² exposed to dogs.

Since the degree of endemicity of Weil's disease is influenced by the murine infection of the rat population, the hydrogen ion concentration of the surface water, a low salinity and a hardness not exceeding 19 to 21, a number of preliminary surveys have been instituted.

With the assistance of the San Francisco Department of Public Health and the Laboratory for Plague Suppressive Measures of the U. S. Public Health Service, both random and spot sampling of 467 rats (*Mus norvegicus*, *Mus alexandrinus*, and *Mus rattus*) yielded in darkfield examinations renal leptospira findings in 176, or 35 per cent. In the vicinity of an animal stable, 42 of 44 old *Norvegicus* rats have been found infected. Single or pooled specimens of the rat kidneys on inoculation into guinea pigs produced the lesions typical for leptospirosis on the first, second, or third passage through these rodents. Twenty-three strains were isolated in culture and by serological tests identified as *Leptospira icterohaemorrhagiae*, generally known as the classical rat strain. Murine leptospirosis had been previously recognized by J. R. Ridlow in San Francisco. Renal leptospirosis infections have been definitely

established in Washington (10 per cent), Nashville (10 per cent), New York (17.2 to 21.9 per cent), Albany (40 per cent), Baltimore (7 per cent), Chicago (3 to 52 per cent), Rochester (38 per cent) and Detroit (16 per cent). The contaminations of water, soil, and food by the urine of these rodents and possibly mice, gophers, or other rodents furnish the seeds for the human infections. Since the intact epidermis is quite resistant to the penetration of the leptospira, the contaminated water must by necessity be brought in contact with the mucous membrane.

In the city with a continuous control of the rat population as a plague preventive measure, the exposures of man to the classical rat leptospira are limited to water accidents, contact with sewage or mud and soil in the vicinity of rodent harborages.

Although the serological tests of the rat strains thus far isolated identify the organisms as indistinguishable from the classical strain studied throughout the world, it is important to remember that other types, probably antigenic variants, may be encountered. The diagnosis of human leptospirosis must employ the serological tests reservedly; just as in typhoid fever the ultimate proof of clinical Weil's disease depends on the isolation of the causative spirochete.

CANINE LEPTOSPIROSIS

The blood serum of a veterinarian, who had an attack of undiagnosed malady complicated by icterus and nephritis 8 months before the test was made, agglutinated *Leptospira canicola* in a dilution of 1:300. More recently, this spirochete has been isolated from the urine of an assistant veterinarian, whose blood clumped and lysed the *Leptospira canicola* in a dilution of 1:10,000 (4+) and 1:30,000 (3+) and *Leptospira icterohaemorrhagiae*

1:100 (4+). In both cases, the epidemiological inquiries strongly incriminated the handling of dogs suffering from "yellow" or Stuttgart's disease. It may, therefore, be appropriate to review the essential facts which have been collected concerning these canine diseases during the past 2 years.

For some time, the hospital of the Society for the Prevention of Cruelty to Animals in San Francisco has noted a high mortality among dog patients suffering from jaundice or severe hemorrhagic gastroenteritis with or without icterus. At the request of Dr. S. T. Michael, 87 dogs, either dead or moribund, have been submitted for examination in order to determine the cause of the illness or death. The prominent autopsy lesions classed the dogs into two types—hemorrhagic and icteric. The former, seen in 38 dogs, resembles Stuttgart's disease or canine typhus, while the latter noted in 42 animals is indistinguishable from "yellows" or canine jaundice. Seven dogs had passed through both types, death occurring while they were in the icteric stage.

Since the gross lesions are in every respect similar to those described by Okell, Dalling, and Pugh,¹² Wirth,¹³ Klarenbeek,¹⁴ and others, and since they will be detailed elsewhere, suffice it to record that leptospira have been demonstrated in the organs of the cadavers of both types in darkfield preparations and properly stained sections prepared from the kidneys, occasionally spleen and liver.

The isolation of these spirochetes offered many difficulties but to date 11 cultures have been obtained from California dogs. Nine were secured directly by culturing the blood from 2 days to a few hours before death or from the clotted blood at the time of autopsy. In two instances, the strains were cultured from the peritoneal fluid or heart blood of very young guinea pigs injected with the emulsion of kidneys

of infected dogs. Failure to culture the leptospira is largely attributable to the heavy bacterial contaminations of the tissues secured from the moribund dogs, and the low pathogenicity of the organisms for guinea pigs. Repeated passages through these rodents are required to induce fatal infections; as a rule, hemorrhages on the viscera and the lungs are noted and a general icterus is very rare.

The isolated leptospira strains are serologically identical with *Leptospira canicola* recognized by Klarenbeek and Schüffner in 1934 in Holland as a specific spirochete of the dog. The independent position of this leptospira has been fully established by Walch-Sorgdrager and Schüffner,¹⁵ who kindly identified the California strains. *Leptospira canicola* is widely distributed and has been found, aside from Holland, in Germany, Austria, and Denmark. Since it has never been isolated from rats, it is generally recognized that this rodent plays no rôle in the dissemination of Canicola infections.

Canine leptospirosis affects all breeds of dog, but rarely under 1 year of age. In California, the highest incidence is noted during the summer with the peak in July and August. The mortality is generally considered high, although accurate figures are not available. In San Francisco, the hospital furnishing the dogs estimates the losses at 80 to 90 per cent. Annually, approximately 150 cases are brought to the clinic for treatment. Fatal infections have been prominent among males; the ratio of the dogs autopsied and sex noted in the histories was males: females 67:18. According to the statistics of Kok in Holland, male dogs are three times more frequently infected than females.

Since it has been impossible to judge the incidence of canine leptospirosis, in particular the Canicola infection in San Francisco and Northern California, a series of serological tests have been un-

dertaken. Of 47 normal dogs obtained from one source, 16 or, 34 per cent, gave serum reactions (1:100 to 1:300,000) indicative of a passed or sub-clinical leptospirosis infection. The dogs of a rural community showed a slightly lower percentage—14.3 per cent or 4 in 28 canines—of latent infections.

Through the courtesy of Dr. Norman J. Pyle of the Lederle Laboratories, Pearl River, New York, the blood sera of 111 dogs, comprising 13 different breeds ranging in age from 1 month to 12 years, were subjected to agglutination and lysis tests with leptospira strains. Ten dogs (9 per cent) agglutinated *Leptospira canicola* in dilutions 1:100 to 1:300,000, while 3, or 2.7 per cent, reacted with *Leptospira icterohaemorrhagiae*.

The existence of canine leptospirosis in the East had been suspected, but it is now proved that both types of leptospira may cause clinical and latent infections in a manner and distribution somewhat similar to that reported from Holland. The observations of Molner and Kasper¹⁶ in Detroit would indicate the existence of canine Weil's disease in the Middle West. As a rule, the Canicola infections overshadow those due to the classical strains. According to Klarenbeek, in 1937, 31 dogs reacted with the *Leptospira canicola* and 21 with the *Leptospira icterohaemorrhagiae* strains. Previous data indicate the following relationship: *Leptospira canicola*: *Leptospira icterohaemorrhagiae* 125:89. On the other hand, in a Danish village, Borg and Petersen and Jacobsen¹⁷ found the sera of 18 in a series of 53 dogs (33 per cent) to give serum reactions indicative of latent classical Weil's disease (*Leptospira icterohaemorrhagiae* serum titers 1:300 to 1:30,000). Only 1 dog of the series reacted with *Leptospira canicola*; he shed the specific spirochete in the urine. Thus 19 dogs, or nearly one-third of the dog population ex-

amined, suffered or had passed through leptospira infection.

The absence of classical strain infections among the canines of San Francisco and California is interesting, and may in some way be associated with the rodent control measures which prevent the hunting of rats by dogs.

The incidence of latent infections increases with age. In dogs over 6 years of age, nearly 60 per cent show the residuals of a latent infection (Kok). The California Canicola leptospirosis is complicated by icterus, and in this respect differs from that seen in Holland. The renal lesions are, however, remarkably similar to those described by Dhont, Klarenbeek, Schüffner, and Voet.¹⁸ In fact, the nephritis, which may lead to acute or subacute fatal uremia, persists following recovery and forms the basis for a leptospiruria for several months.

It is this shedder stage with the *Leptospira canicola* which doubtless maintains the epidemization of the dog population in form of acute and fatal, atypical, abortive, and latent infections. Since the dog exhibits great interest for the urine and the genitalia of its own species, the infection is doubtless spread by contact directly through the tongue or nose. This behavior is preëminent among male dogs and thus explains the higher incidence. Sexual intercourse may equally be a factor. General uncleanliness may lead to the infection of an entire dog family and to clinical or latent human cases.

HUMAN "LEPTOSPIROSIS CANICOLARIS" OR CANICOLA FEVER

The two observations on Canicola fever in California may be classed with the occupational diseases. Both the veterinarian and, in the second case, an assistant in a dog pound handled a great many (about 150 annually) dogs suffering from leptospirosis. However, it is not unlikely that Canicola fever

is more widely prevalent than is indicated from the available records. Mild cases are difficult to diagnose and Canicola infections, without any icterus, prevalent among dogs may readily cause atypical or abortive cases in the owners (Roos, Walch-Sorgdrager and Schüffner).¹⁹

Without a special bacteriological examination, an influenza or undulant fever-like disease or a meningitis may be suspected as a Canicola infection provided the inquiry discloses an association with dogs. During the past 3 years, the diagnosis of Canicola fever has been established for 12 human beings living in Holland. At least 6 cases have been recognized in Denmark. Brammer, Petersen, and Scheel-Thomsen²⁰ traced the infection of a 25 year old housemaid with signs suggestive of undulant fever or miliary tuberculosis, but with a Canicola serum titer of 1:300, to a 7 month old puppy which lived in the house and suffered from an acute attack of nephritis. The persistent dysuria which followed forced the maid to mop up after the dog several times a day.

WEIL'S DISEASE TRANSMITTED FROM DOGS

Aside from the 20 cases of Canicola fever thus far reported from Holland, Denmark, and the United States, human Weil's disease caused by the classical strain transmitted from the dog to man have been reported. The two infections described by Krumbein and Frieling²¹ and one by Montagu Lawrence and Okell²² have not been proved bacteriologically. On the other hand, the fourth case seen by Borg and Petersen and Jacobsen in a plumber was traced to his pet dog, an 8 month old "Rattler Pinscher" with serum titer for the classical strain of 1:30,000 and positive findings of spirochetes in the urine. Two cases of Weil's disease in Detroit are doubtless of canine origin.

LATENT LEPTOSPIROSIS

In view of the widespread and regionally high incidence of murine and canine leptospirosis, it is reasonable to suspect that aberrant human infections due to water accidents, etc., and due to association with diseased subclinically infected dogs may be more frequently encountered than the present reports would indicate. The finding of leptospira antibodies by Mason²³ in the sera of 6 out of 11 rat catchers, none of whom recollected having been jaundiced, strongly suggests the existence of latent infections.

In San Francisco, 1 of 10 sanitarians engaged in rodent control work agglutinated *Leptospira icterohaemorrhagiae* in a dilution 1:300.

Roos,¹⁹ in an intriguing report on Canicola fever in a family, discovered with the aid of the serologic tests two additional contact infections in a young adult and child, who apparently had passed through a leptospirosis diagnosed as influenza. The original case, which led to the discovery of the focus, suffered from meningitis. These and other less carefully investigated mysterious illnesses rather forcibly indicate that human Canicola disease may masquerade in a community in form of atypical, abortive, and subclinical infections. It is, therefore, recommended that in future all sera submitted to public health laboratories for the Widal or Brucella reaction be subjected to tests with different leptospira strains.

Since at least 40 per cent of the human Weil's infections may not be accompanied by an icterus, the extent of this disease of murine or even canine origin requires further investigation. However, in this connection, it is imperative to extend a word of warning. The bacteriological diagnoses of leptospirosis, in particular the serological tests, require considerable experience and judicious interpretation. Théy

should be, therefore, entrusted to a few properly qualified laboratories.

The facts here recorded amply attest to the increasingly important fact that the animal kingdom is a reservoir of disease.

Special Syringe for Skin Tests

THOMAS B. MAGATH, M.D.

*Division of Clinical Pathology, Section on Parasitology
The Mayo Clinic, Rochester, Minn.*

THERE are several tests which are commonly conducted on a large scale in the interest of public health, which consist of the injection, intracutaneously, of 0.1 cc. of fluid, usually into the skin of the forearm. The most common, of course, are the Mantoux, Schick, and Dick tests. For conducting such tests on a large scale it is customary to fill a tuberculin syringe or other syringe of a similar nature and to give injections to a series of patients successively, changing the needle before each injection. By this method, as commonly practised, the first individual receives a "full" 0.1 cc. and thereafter individuals receive 0.1 cc. less the amount present in the shank of the needle. If one corrects for this he has a choice of either wasting a large amount of the test material in order to begin each injection on the line, or of using interval markings on the syringe, which frequently leads to considerable error. A number of syringes which are calibrated only in tenths of a cubic centimeter and especially made for this purpose will not permit correction at all. It may be rightly suggested that certain discrepancies in reports have been due to errors caused by this method of procedure when a large group has been tested.

In order to overcome this difficulty a syringe* has been especially devised which takes into account the loss of

fluid in the needle shank. The syringe is made of special resistant glass and

FIGURE I—Special syringe for use in various skin tests, when the same test is being given to large numbers of persons

can be sterilized, either by boiling or by dry baking. It is calibrated to deliver eight doses of 0.1 cc. each, and has primary and secondary markings. Between the primary and secondary markings there is sufficient fluid to fill the shank of a $\frac{5}{8}$ inch, 26 gauge needle. The procedure of injecting is to fill the syringe to the last mark; the first dose is administered by pushing the plunger to the first secondary marking. A new needle is put on and the plunger is pushed in to the second primary marking, thus filling the needle. The second injection is made by administering the contents of the syringe down to the second secondary marking, and so on, until the eight doses are administered. With the use of this syringe the patient gets exactly 0.1 cc. without any danger of misreading the amount.

* This syringe has been especially made by the Becton-Dickinson Co., Rutherford, N. J.

Revision of Methods and Standards for Certified Milk*

J. HOWARD BROWN, PH.D.

*Department of Pathology and Bacteriology, Johns Hopkins University,
Baltimore, Md.; Chairman of the Committee on Methods and
Standards of the American Association of Medical
Milk Commissions*

IT seems appropriate that a representative of the American Association of Medical Milk Commissions, a pioneer organization for raising the standards of milk production, should inform the American Public Health Association of progressive changes in Methods and Standards for the Production of Certified Milk.† These methods and standards are revised annually and the production of certified milk may be regarded as a laboratory in which new methods of practical value to the entire dairy industry may be introduced and tested. Such has been the case with the control of tuberculosis, of Bang's disease, and of hemolytic streptococcus infections transmissible from man to the cow and from the cow to man.

In May, 1936, an improved medium for making plate counts of bacteria was adopted for certified milk. A year later the results of using this medium in comparison with the standard nutrient agar of the A.P.H.A. were reported and published in the *American Journal of*

Hygiene (January, 1938). Since then, and on a more limited scale, the new medium has been compared with not only standard nutrient agar but also the "tryptone glucose skim milk agar." The results may be summarized by a quotation from an article in the *American Journal of Public Health* (September, 1938) which reads

A.A.M.M.C. agar . . . has been found to yield considerably higher counts than does the standard nutrient agar of the A.P.H.A., counts of the same magnitude as may be obtained with the "tryptone glucose skim milk agar" . . . The improved medium not only gives a bacterial count that is more nearly true but its adoption serves, in effect, to raise the standard for certified milk.

The A.A.M.M.C. agar in dried form may be obtained from two manufacturers, The Baltimore Biological Laboratory and the Difco Laboratories. At this point it is gratifying to be able to say that since the adoption of this medium the quality of certified milk has continued to improve. In the *Methods and Standards for Certified Milk*, meat infusion agar plus blood is suggested as an alternative medium for making total bacterial plate counts. This medium serves also to reveal the presence of hemolytic streptococci. Blood agar is especially suitable for the examination of unpasteurized certified milk since

* Read before the Laboratory Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 28, 1938.

† Copies may be obtained from the American Association of Medical Milk Commissions, Inc., 1265 Broadway, New York, N. Y.

such milk is relatively free from all bacteria other than those which come from the udder. It may not be suitable for grades of milk which are more subject to exogenous contamination by saprophytic bacteria. I should be interested to know what the effect of incubation of agar plates at temperatures lower than 37°C . might be on the bacterial plate counts of certified milk. It might be that the kinds of bacteria found in such milk would not grow so well at lower temperatures as do those found in other grades of milk. Whatever media or temperature may be used, I believe that the American Association of Medical Milk Commissions will favor those methods which give the highest counts.

The determination of coliform counts is being found useful for the control of certified milk production. It is required that certified milk—raw shall not contain more than 10 coliform organisms per cc. and certified milk—pasteurized shall contain no coliform organisms. It is interesting to find that a high coliform count is not always associated with a high total bacterial count. It is in these instances that the coliform count is an indication of a break in the technic of milk production or handling and usually it can be found. Sometimes it is in the cleaning of udders, sometimes in faulty milking, sometimes in dusty stables, sometimes in a faulty valve or dead end of pipe, sometimes in imperfectly sterilized bottling machinery or bottles. In pasteurized milk the presence of coliform organisms indicates either ineffective pasteurization or subsequent contamination of the milk. For a high grade milk the coliform count is a good trouble detector although it is admitted that even the finding of *Escherichia coli* does not have the same significance in milk as in drinking water.

The spore test is of considerable value in maintaining the cleanliness of

certified milk. Pasteurization does not sterilize milk, nor does it kill all of the vegetative bacteria in milk. If, however, milk is heated at 80°C . (176°F .) for 15 minutes the vegetative bacteria are killed and only the spores remain alive. This test for the cleanliness of milk was described by Weinzirl and Veldee in the *American Journal of Public Health* in 1915 and 1921. It is now included in *Methods and Standards for Certified Milk*. I think it must be admitted that if of ten tubes of 10 cc. each of undiluted milk subjected to the spore test, few or none show any bacterial growth, it must be a very clean milk.

The identification of hemolytic streptococci whether in milk or in human throats has been greatly simplified and the time required shortened by the precipitin grouping of Lancefield. The technic referred to in the 1938 edition of *Methods and Standards* and the availability of grouping sera bring this method within the reach of diagnostic and milk control laboratories.² It is now possible to determine the serological group to which a hemolytic streptococcus belongs within 48 hours after the throat swab or milk sample is taken. Simple cultural methods are also described which correlate closely with serological differentiation.

A valuable contribution to the technic for the routine examination of throat swabs in blood agar is the "streak-pour" plate which has been in use at the laboratory of the Maryland State Department of Health for some time. As described in *Methods and Standards* for 1938, the method is as follows.

Streak the swab across one edge of the solidified surface of a nutrient agar plate (preferably infusion agar without blood or dextrose). With the wire loop streak the material from the original streak over the remaining surface of the agar. Over the inoculated surface pour not more than 5 cc. of melted blood agar.

FIGURE I—A blood agar plate streaked with a throat swab. Most of the hemolytic surface colonies were of staphylococci. It was extremely difficult to find any streptococci.

FIGURE II—A "streak-pour" blood agar plate inoculated with the same throat swab as was the plate shown in Figure I. There were some hemolytic surface colonies of staphylococci at the periphery of the plate but the deep hemolytic colonies were of streptococci. As is often the case, the deep colonies of staphylococci were non-hemolytic.

Although for the recognition of streptococci nothing is better than a "pour" plate of properly diluted material, the "streak-pour" plate reduces the labor, saves time, and eliminates the chance involved in making a proper dilution from the swab. It is far superior to the ordinary "streak" blood agar plate as may be illustrated by the Figures I and II.

The certified milk industry is becoming mastitis conscious. I do not refer to the rare cases of mastitis caused by the infection of an udder by a hemolytic streptococcus of human origin which may cause an outbreak of septic sore throat or scarlet fever. In the entire 45 years of the history of certified milk only one such outbreak has occurred and that was 12 years ago, before present methods of control were known or in effect. I refer rather to the ordinary barnyard variety of mastitis which is so common in dairy cattle

throughout the world and the streptococci of which do not cause epidemics among consumers of the milk. Nevertheless, largely for economic and esthetic reasons, progress is being made in the control of bovine mastitis and its elimination from certified milk herds. Beginning this year more detailed herd records are required, the milk of cows entering or reëntering certified milk production is required to undergo bacteriological examination, and an attempt has been made to place the various tests which have been proposed for the early detection of mastitis in their proper perspective.

Safety is only one of the qualities of a superior milk. There are possibilities of improving the flavor and nutritive quality of milk. Flavor may be

a matter of taste and habit but it is now known that the butter fat content is not the only variable nutritive factor in milk although it may be the most obvious one. It is well known that the diet of the cow affects the nutritive quality of her milk, that the winter milk of cows fed on dry feed is inferior to the summer milk of the same cows fed on green pastures. Recently it has also been demonstrated that many of the qualities of summer feed may be preserved for winter feeding by such methods as the rapid artificial drying of hay, the preserving of grasses by molasses (molasses ensilage) or acids (A.I.V. ensilage) and that the vitamin D content of milk may be increased at will by the feeding of irradiated yeast. By such methods winter milk may be made equal to summer milk. This line of progress in dairying is in the making,

is the subject of special instructions issued to the producers of certified milk, and is being followed by many of them.

In conclusion I would urge health officials to take a broader interest in milk than to make it safe. I am convinced that under proper supervision safe raw milk may be produced. In the effort to produce such milk many fundamental problems of milk production become incentives. The solution of these problems is of benefit to the entire dairy industry and to the consuming public. Your coöperation in maintaining the methods and standards for the production of certified milk is invited.

Time Lost by Industrial Workers from Disabling Sickness and Accidents During the Early Days of Disability*

WILLIAM M. GAFAFER, D.Sc.

*Senior Statistician, United States Public Health Service,
Washington, D. C.*

ONE of the sources of industrial disability data used for a number of years by the Division of Industrial Hygiene of the National Institute of Health is the records of industrial sick benefit organizations. Since the majority of these organizations subscribe to a 7 day waiting period, that is, 7 days must elapse between the onset of disability and the commencement of the payment of benefits, the records of such organizations contain no information on disabilities lasting 7 days or less,¹ and hence the published reports on this material concern themselves only with disabilities lasting 8 days or longer. This situation frequently raises the question of the magnitude of the time lost from short disabilities, and its relation to time lost from disabilities of all durations. An opportunity to study the question presented itself when the requisite data were made available by the record of one day absences or longer that occurred among the employees of

a public utility company in Massachusetts.

For a quarter-century this company has been operating under a liberal disability benefit plan which provides for payment of wages in full or in part during disability beginning with the first day of absence. During the second 6 months of membership an employee is allowed accumulated sick leave of one day per month at full pay. After the first year of membership full pay for continuous disability is allowed for 15 weeks; beyond this time three-fourths to one-fourth of the employee's wages are paid, the period of payment depending upon the number of years of employment with the company. However, for present purposes, all cases of continuous disability extending over 372 calendar days were automatically considered closed at the end of the 372nd day. In all instances *days* refer to calendar days, and absences of less than one full calendar day are omitted.

The analysis covers the 5 years, 1933-1937. The number of male person-years of membership was 12,969, while the number for females was 3,272. This membership is equivalent to the exposure for one year of 12,969 males and 3,272 females. In the analysis no

⁴ Number of absences: Males, 1,923; females, 976. Number of days of disability: Males, 12,542; females, 4,970.

⁵ Number of absences: Males, 1,952; females, 1,659. Number of days of disability: Males, 31,854; females, 10,145.

⁶ Number of absences: Males, 592; females, 252. Number of days of disability: Males, 7,994; females, 2,627.

⁷ Number of absences: Males, 228; females, 11. Number of days of disability: Males, 6,593; females, 441.

reference is made to the age of the employees. It is sufficient to state at this time that according to the Bureau of the Census² the native white gainful male workers in 1930, under 35 years of age constituted 47 per cent of the total of ages 18 through 69 years, while the corresponding percentage for females was 64, and that in the instance of the present group of employees, the corresponding percentages for males and females, respectively, were 42 and 68. For male employees the number of absences lasting one calendar day or longer from all disabilities which ended during the 5 year period was 11,672 with 97,504 days of disability, and for female employees, the corresponding figures were 5,956 and 35,518, respectively. The causes of disability have been broadly grouped into respiratory diseases, digestive diseases, nonrespiratory-nondigestive diseases, nonindustrial accidents, and industrial accidents. Approximately 13 per cent of the absences were diagnosed by the company physician, 72 per cent by the plant nurse, and 15 per cent by the patient.

Table I shows, by sex and broad cause group, the frequency of absences together with the percentage of total days of disability for each day after onset of disability through the 21st day. This table contains all of the fundamental data necessary for the analysis, the development of the figures which are shown later, and the determination of the actual numbers upon which rates are based. To conserve space no tables derivable from Table I will be presented. In some instances, and these will be indicated in the titles to the figures, a simple calculation will be necessary to yield a particular figure. It should be borne in mind that for a specific day after onset of disability, the number of absences is the same as the number of employees absent, and the number of days absent, respectively.

ANALYSIS OF DATA

Percentage distribution, according to broad cause groups, of days lost on specific days of disability after onset—Figure I shows for both sexes the percentage distribution, according to broad cause groups, of days lost on specific days of disability after onset through the 21st day of disability. Thus among the males, of the total first-days lost, 60 per cent were accounted for by the respiratory diseases, 16 per cent by the digestive diseases, almost 17 per cent by the nonrespiratory-nondigestive diseases, 5 per cent by nonindustrial accidents, and 2 per cent by industrial accidents. The pattern of the figure is determined by the duration and frequency of the various disabilities entering the 5 cause groups. Thus if all of the disabilities had lasted 21 days, and if the same frequency had been yielded by each cause group, the resulting pattern would consist of 5 rectangles of equal area.

Among the males the percentage for the respiratory diseases ranks first in magnitude on each of the first 13 days, the percentage rising from 60 on the first day to 62 on the 3rd day and then gradually decreasing to 33 per cent on the 13th day. During this period the percentage for the nonrespiratory-nondigestive diseases gradually increases from 17 to 33 per cent, thus on the 13th day equalling the percentage for the respiratory diseases. On the 14th day and on each day thereafter the percentage for the nonrespiratory-nondigestive diseases is sufficiently large to assume first place among the percentages corresponding to the different cause groups. In the instance of the females the same phenomenon is evident not on the 14th day but on the 20th on which day the percentage for the respiratory diseases has dropped to 36 and the percentage for the nonrespiratory-nondigestive diseases has increased to 37. The observable sex

FIGURE I—Percentage distribution, according to broad cause groups, of days lost on specific days of disability after onset, employees of a public utility, 1933-1937. (Plotted points calculated from Table I.)

difference with respect to the non-respiratory-nondigestive diseases during the first 2 days is probably accounted for by dysmenorrhea.

The percentages for the digestive diseases are of a lower order of magnitude beginning, among the males, at 16 per cent, falling to a minimum of 8.7 per cent on the 5th day, and gradually increasing to 17 per cent on the 21st day: the behavior of the percentages among the females is approximately similar to that of the males.

The percentages for nonindustrial accidents among the males gradually increase from 5 per cent on the first day to 11 per cent on the 21st day, and among the females the corresponding increase is from 4 to 10 per cent. Among the males the percentages for

industrial accidents gradually increase from 2 to 11, while among the females they never become greater than 0.74 per cent during the first 21 days after onset of disability.

Frequency of absences, according to broad cause groups, on specific days of disability after onset—The frequency of absences from broad cause groups on specific days of disability after onset through the 21st day of disability is shown, among other things, in Table I, and graphically in Figure II (left-hand scale). It will be observed that with respect to all disabilities among the males there is an orderly decrease from 900 absences per 1,000 on the first day of disability to 59 on the 21st day; the females, however, on the first day yield a frequency of over 1,800 which de-

creases at a similar rate to 83 on the 21st day. Thus the females show a higher incidence than the males throughout the first 3 weeks of disability, but as duration increases the proportionate difference decreases; beyond the 21st day the difference becomes zero and finally negative. Although the males experienced 900.0 first day absences per 1,000 and the females 1,820.3 per 1,000, only 153.1 absences per 1,000 for males (17 per cent), and 231.7 absences per 1,000 for females (13 per cent) extended through the 8th day. It is of interest to observe the percentage composition of these 8th day absences by cause group (Figure I). Of the 153.1 8th day absences per 1,000 among males 46 per cent are accounted for by respiratory diseases, 28 per cent by nonrespiratory-nondigestive diseases, 10 per cent by digestive disease, 9 per cent by nonindustrial accidents, and 7 per cent by industrial accidents; the corresponding percentages for the females are, respectively, 56, 26, 10, 7, and 0.7.

Of interest also is the percentage of first day absences continuing through the 8th day according to cause group. With

the use of data in Table I it will be found that of the first day absences from industrial accidents among the males, 64 per cent continued through the 8th day, the corresponding percentage among the females being 44.

FIGURE II—*Left-hand scale:* Annual number of absences per 1,000 persons according to broad cause groups on specific days of disability after onset, employees of a public utility, 1933-1937. (Plotted directly from Table I. The vertical scales for males and females, respectively, are different. The industrial accidents among the female employees are not shown.) *Right-hand scale:* Per cent of total days of disability (1933-1937) corresponding to each day of disability after onset. (Plotted points calculated from Table I.)

The corresponding percentages for males and females, respectively, with respect to the other cause groups are, nonindustrial accidents, 31 and 22 per cent; nonrespiratory-nondigestive diseases, 28 and 12 per cent; respiratory diseases, approximately 14 per cent for both sexes; and digestive diseases, 10 and 8 per cent.

Percentage of total days of disability (1933-1937), according to broad cause groups, on specific days of disability after onset—The right-hand scale of Figure II shows for each broad cause group the percentage of the total days of disability (1933-1937) on specific days after onset of disability. Thus with regard to all disabilities, 12.0 per cent of the total days of disability among the males occurred during the first day after onset while the corresponding percentage for the females is 16.8, both percentages decreasing in an orderly manner to less than 0.8 per cent on the 21st day. The difference between the percentages for males and females becomes rapidly smaller as duration increases to the 5th day; thereafter the differences approximate zero, and finally become negative.

The daily percentage contribution of each broad cause group to the total days of disability graphically presented in Figure II shows that the percentages for each cause group gradually decline during the first 21 days of disability. Thus in the instance of the respiratory diseases among the males the percentage declines from over 7 on the first day to less than 0.2 on the 21st day; among the females the decline is from nearly 9 to less than 0.3 per cent. The percentage for the digestive diseases on the first day is less than 2 for the males and almost 3 for the females; both percentages become approximately 0.1 on the 21st day. For the nonrespiratory-nondigestive diseases the percentages on the first day for males and females, respectively, read 2 and 4.6, declining in

both instances to less than 0.3 on the 21st day. Nonindustrial accidents among the males and females, respectively, contribute 0.6 and 0.7 per cent on the first day and decline to 0.09 and 0.08, respectively. Finally, among the males industrial accidents yield 0.23 per cent on the first day and 0.09 per cent on the 21st, the corresponding percentages for the females (not shown in the figure) being 0.03 and 0.01, respectively.

Figure III shows the result of placing end to end the first 7 bars of Figure II. These bars, as indicated previously, represent for each sex and for each of the first 7 days of disability after onset, the percentage contribution to the total days of disability (1933-1937) by all cause groups and by specific cause groups. In particular the figure reflects an important sex difference, namely, the higher frequency among the females of absences of short duration. Thus in the instance of the males nearly 45 per cent of the total days of disability are accounted for by the first 7 days while the corresponding percentage for the females is over 52. The largest differences of the percentages with respect to sex occur in order of decreasing magnitude on the first, second, and third days, respectively.

Annual number of days lost per person from onset of disability through the 21st day after onset, or during any selected interval within these end points—The cumulative number of days of disability per 1,000 persons (annual basis) for specific days after onset is shown in Table I by sex, and broad cause group. It will be observed that the annual frequency for all causes increases from 0.9 day per male on the first day to 7.5 days per male for the total period of 372 days: the corresponding rates for females are 1.8 and 10.9. During the first 7 days the annual frequency is 3.4 days per male and

FIGURE III—Per cent of total days of disability (1933-1937) according to broad cause groups on specific days of disability after onset. (Bars for the first 7 days of Figure II placed end to end. The industrial accidents among the female employees are not shown.)

5.7 per female. These frequencies together with those for the different broad cause groups are shown graphically in Figure IV from onset of disability through the 21st day after onset; in Figure IV-A the frequencies corresponding to all causes and the different cause groups are compared for the males and females, respectively, while in IV-B the frequencies for the males and females are compared for all causes and each cause group, respectively. It will be observed in IV-A that the curves for the different cause groups are arranged in the same order regardless of sex, and that in IV-B, with the exception of industrial accidents, the curves for the females for each cause group lie above the corresponding ones for the males.

From Figure IV it is possible to determine approximately, and more precisely from Table I, for either sex and for all causes or for specific cause

groups the annual number of days lost per person for any chosen interval of time within the first and 21st days after onset of disability. Thus if the interval is defined by the 8th and 12th days it is necessary only to find the difference between the appropriate cumulative frequencies shown for the 7th and 12th days, respectively.

Percentage of total days lost (1933-1937) from onset of disability through the 21st day after onset, or during any selected interval within these end points—Calculations based on figures recorded in Table I show that of the total number of 97,504 days lost by the males 39 per cent are accounted for by the respiratory diseases, 33 per cent by the nonrespiratory-nondigestive diseases, 13 per cent by the digestive diseases, 8 per cent by nonindustrial accidents, and 7 per cent by industrial accidents. The corresponding per-

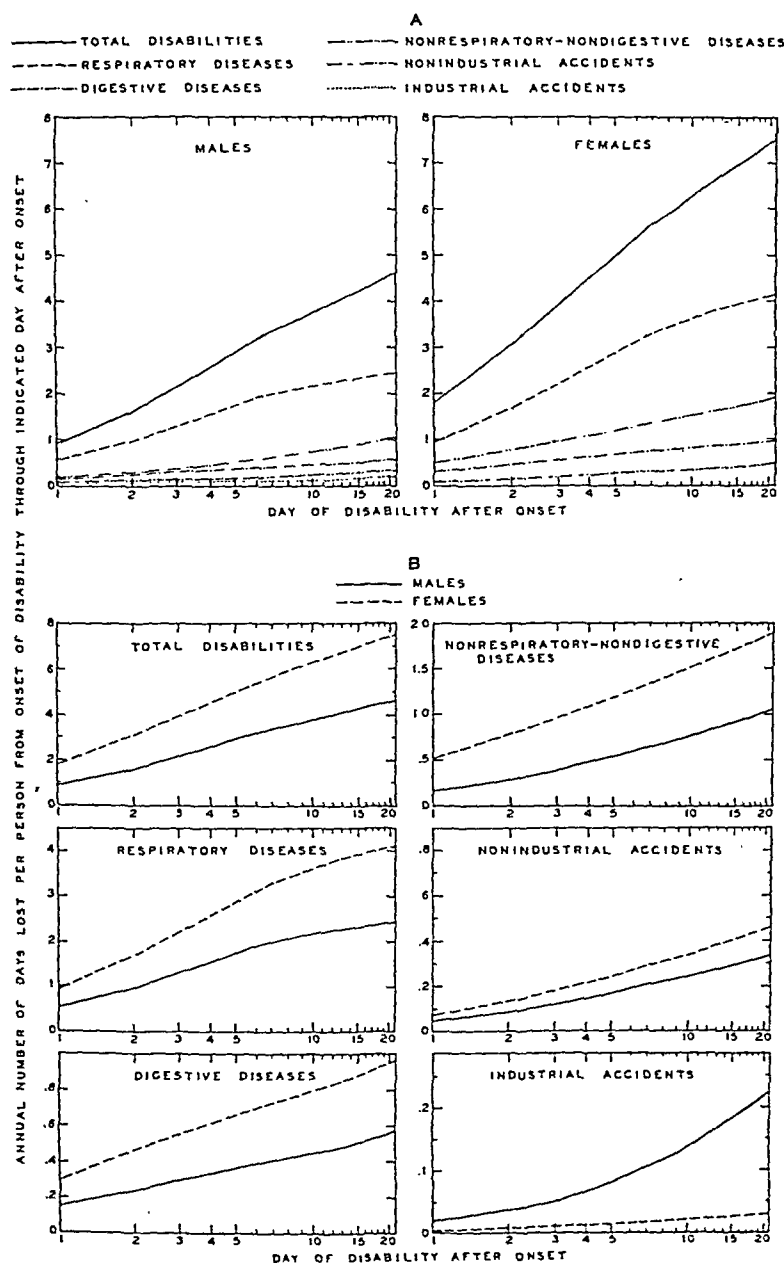

FIGURE IV — Annual number of days lost per person from onset of disability through the indicated day after onset, according to broad cause groups, employees of a public utility, 1933-1937. (Plotted from Table I after dividing the appropriate figures by 1,000. Logarithmic horizontal scale. Note changes in the vertical scale in passing from A to B.) A. Frequencies corresponding to all causes and the different cause groups compared for males and females, respectively. (The industrial accidents among the female employees are not shown.) B. Frequencies for males and females compared for all causes and each cause group, respectively.

centages for the females who lost a total of 35,518 days are, respectively, 49, 29, 14, 7, and 1.

The foregoing percentages are cumulative covering the first 372 days after onset of disability. Of interest are the cumulative percentages for specific days after onset of disability. By transforming the vertical scales of Figure IV-A for the males and females, respectively, these cumulative percentages will be shown graphically by the

curves as drawn.* Thus 44.57 per cent of all days of disability among the males occurred during the first 7 days, the respiratory diseases, nonrespiratory-nondigestive diseases, nonindustrial accidents, and industrial accidents, respectively, accounting for 26.62, 8.44, 5.42, 2.72, and 1.37 per cent of all days

* One unit on the vertical scale for the males, Figure IV-A, is equivalent to 15.30 per cent; for the females, the equivalent is 9.21 per cent.

lost; among the females the corresponding percentages for all causes and specific cause groups are, respectively, 52.26, 30.33, 12.40, 6.72, 2.67, and 0.14. If the vertical scales of Figure IV-A are transformed as previously indicated, the cumulative percentages of all days lost may be read for all causes and each cause group for any interval after onset of disability within the first 21 days.

Thus far in this section the examination of cumulative percentages of days lost has been restricted to the universe of all days lost (1933-1937) and the days lost on account of each cause group were related to this specific universe. The remainder of the section will be devoted to an examination of cumulative percentages related to component universes representing all days lost from the respective cause groups, the object being to present sufficient material that will enable the reader to answer questions such as the following: What percentage of all days lost from the respiratory diseases occurred during the first 7 days after onset? What is the magnitude of the interval in days after onset that accounts for 50 per cent of the days lost from the respiratory diseases?

The cumulative percentages suggested are shown in Table I and are presented graphically in Figure V. In Figure V-A the cumulative percentages corresponding to all causes and the different cause groups are compared for males and females, respectively, while in Figure V-B the cumulative percentages for males and females are compared for all causes and each cause group, respectively.

It will be observed in Figure V-A that the cumulative percentage curves cross each other in some instances; it is not possible, therefore, to arrange the curves in any definite order. With respect to the males the curves rise, with the exception of the curve for respiratory diseases, within a band ap-

proximately 25 per cent wide, while the curves for the females, with the exception of the one for industrial accidents, rise within a band of similar width.

In the comparison of the sexes with respect to cause group, shown in Figure V-B, it is seen that the curve for the males lies consistently above that for the females in the instances of the respiratory diseases and industrial accidents, respectively; with respect to the remaining cause groups and all causes, the curve for the males lies consistently below that for the females. Apparently the most striking sex difference is shown by the nonrespiratory-nondigestive diseases; in this instance the curve for the females after the second day after onset lies consistently above that for the males at a distance equivalent to approximately 20 per cent on the vertical scale. This means that of all days lost and accounted for by the nonrespiratory-nondigestive diseases the females lost a greater proportion during the early days of disability than the males. For example, 60 per cent of such days were lost by the females during the first 21 days after onset of disability while the corresponding percentage for the males is 42.

The question now arises of the percentage of days of disability accounted for by the first 7 days after onset of disability. These percentages for the males and the females, respectively, are for each cause group as follows: respiratory diseases, 67 and 62; digestive diseases, 42 and 48; nonindustrial accidents, 33 and 36; nonrespiratory-nondigestive diseases, 26 and 44; and industrial accidents, 21 and 11. As stated previously the corresponding percentages for all causes are 45 for the males, and 52 for the females.

Another question of interest with respect to all causes and each cause group concerns the specific day of disability after onset on which the cumulative percentage of days lost attains the

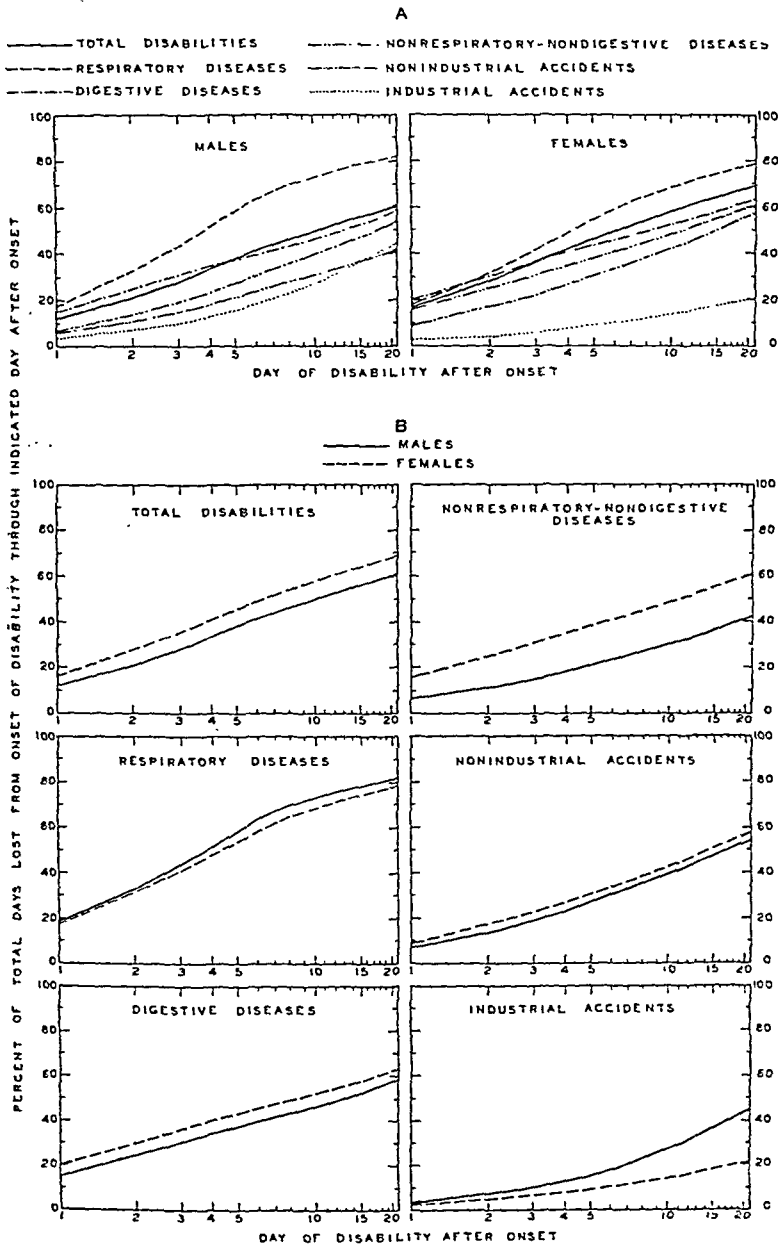

FIGURE V — Percentage of total days lost (1933-1937) from onset of disability through the indicated day after onset, according to broad cause groups, employees of a public utility, 1933-1937. Each broad cause group is considered a universe; thus in the instance of the respiratory diseases the male employees lost on the first day of disability 18 per cent of their total days of disability caused by the respiratory diseases. (Plotted directly from Table I. Logarithmic horizontal scale.) A. Percentages corresponding to all causes and the different cause groups compared for males and females, respectively. B. Percentages for males and females compared for all causes and each cause group, respectively.

value of approximately 50 per cent. This particular day for all causes is the 10th for males, and the 6th for females. The particular days for the specific cause groups for males and females, respectively, are: respiratory diseases, 4th day, both sexes; digestive diseases, 12th day and 8th day; nonindustrial accidents, 17th day and 15th day; nonrespiratory-nondigestive diseases, after the 21st day, and 11th day; and industrial accidents, both sexes after the 21st day.

SUMMARY

Reports on sickness and accidents causing disability lasting one calendar day or longer and ending during the 5 years, 1933-1937, among the employees of a public utility furnish the requisite data for the study of the relation of time lost from disabilities lasting less than 8 calendar days to the total time lost from all disabilities. This relation is important since the majority of sick benefit organizations subscribe to a 7 day waiting period and thus the

records of these organizations contain no information on cases of less than 8 calendar days' duration.

The 12,969 male person-years of membership in the benefit plan yielded 11,672 absences which accounted for 97,504 days of disability while the 3,272 female person-years yielded 5,956 absences which accounted for 35,518 days of disability.

Of the total days of disability from the respiratory diseases, 67 per cent among the males, and 62 per cent among the females, occurred during the first 7 days of disability after onset. The corresponding percentages for the males and females, respectively, for each of the remaining cause groups are as follows: digestive diseases, 42 and 48; nonindustrial accidents, 33 and 36; nonrespiratory-nondigestive diseases, 26 and 44; and industrial accidents, 21 and

11. The corresponding percentages for all causes are 45 for the males, and 52 for the females.

Charts and data are presented which make possible the determination of the percentage of total days lost during any interval within the first 3 weeks after onset of disability. Thus while the report deals principally with the possible effect of a 7 day waiting period on recorded lost time from disability sufficient material is presented which yields information on the possible effect of a waiting period of any length up to and including 21 days.

DISCUSSION

RICHARD D. MUDD, PH.D., M.D.

Medical Director, Chevrolet-Grey Iron Foundry; and Chevrolet-Transmission, Divisions of General Motors Corporation, Saginaw, Mich.

IN discussing Dr. Gafafer's paper I could limit myself to one sentence. He has set up an excellent pattern for the representation of morbidity conditions of an industry and has made it possible to compare one industry with another in a uniform way. He has done more than this. He has shown us the relationship between the time lost during the first 7 days of disability and that after 7 days; the broad causes of this time lost and the important influence of sex on disabilities according to broad causes and length of disability.

I will limit myself to his statistics for males because the foundry group I wish

to compare with his is composed of 94 per cent males.

Dr. Gafafer has by his statistical treatment of disability during the first 7 days, opened an entirely new and important field of industrial medicine in its relation to public health. He has demonstrated clearly that when we fail to keep a record of disabilities of 7 days or less we are missing 44 per cent or more of the days of disability in males due to sickness or injury in industry. How many would have realized that the days of disability occurring prior to the 8th day would have amounted to such a large percentage of total days of disa-

bility? When these days of disability prior to the 8th day are broken down into their broad causes the results are more significant. For example he has shown us that by the 4th day, 50 per cent of the days of disability due to respiratory diseases has occurred, and that by the 7th day 67 per cent of disabilities due to respiratory disease has occurred.

In connection with this disability during the early days of illness or accident a serious problem presents itself—the difficulty of recording disabilities of short duration. If an industrial plant is operating 5 days a week an employee can be disabled 2 days without losing any working time. The problem is more serious if the plant operates 4 days or less. I think the time has come when we in industrial medicine should disregard working time lost as a measure of industrial health. The important thing to us as custodians of industrial health is how many days are our patients—the industrial employees—disabled and how many disabilities have they per year. I do not have time to discuss the various means of solving this difficulty of detecting and recording these disabilities of short duration. I can only suggest that the ultimate solution may depend either on payment of benefits for disability of one day or more, as in Dr. Gafafer's group, or upon excellent coöperation of employees and the Industrial Medical Departments.

For several years I have been intensely interested in the problem of recording time lost by industrial workers from disabling sickness and accidents during the early days of disability. For 3 years we recorded on a special card every disability we knew of regardless of whether working time was lost or not. These cards were filed with the employees' records. In a rudimentary way we classified this time lost by departments. It was a good experience

for our later efforts. For the past 2 years, however, in addition to recording all disabilities of any length, even 1 day or more, on an employee's examination card, we have been submitting all disabilities of 3 days or more to statistical study by occupational groups, for the industry as a whole and by cause. The recording of these short disabilities in the records of individual employees gives us important early clues to the employee's health and helps us to forestall longer and more serious disabilities, and thereby materially promotes public health. I will not take your time to explain the various means we have employed to discover these disabilities but, suffice it to say, that we have followed every lead. It has been a severe task, requiring a great deal of clerical help and attention to details. For those who find it difficult to record these disabilities it is suggested that every employee who loses one day or more from work or who is known to have been disabled, even if he lost no time, should be approved by the medical department. We have ceased to record days of disability after the 150th day, which suggests that our statistics for a certain month cannot be completed until 5 months after the last day of that month.

I thought it would show the importance of recording these early days of disability if I compared my results with those of Dr. Gafafer. Table I compares the experience of an iron foundry employing an average of 5,000 people 94 per cent of whom are men, with Dr. Gafafer's figures for *Mcn.* You will note that the number of disabilities and days lost per 1,000 employees from the 3rd to the 7th day inclusive in Dr. Gafafer's group is considerably in excess of that for the foundry. This excess of short disabilities and early days of disability demands an explanation. It can be explained in two ways: (1) that we have

TABLE I
Annual Number of Absences per 1,000 Employees

Days of Disability After Onset	Grey Iron Foundry—94% Males		Public Utility (Dr. Gafafer's Figures)	
	Daily	Cumulative Days of Disability	Daily	Cumulative Days of Disability
1st	?		900.0	900.0
2nd	?		695.3	1,595.3
3rd	376.6	1,129.8	543.2	2,138.5
4th	325.8	1,301.0	415.4	2,553.9
5th	283.0	1,426.0	329.4	2,883.3
6th	258.0	1,786.0	262.1	3,145.4
7th	198.0	1,912.0	205.6	3,351.0
150th		5,770.0	(To 372nd day)	
			2.2	7,518.2

Days Lost per M per Year—

Dr. Gafafer's Figures	7,518.2	(Public Utility)
Dr. Mudd's Figures (Omitting 1 & 2 day disability).....	5,770.0	(Iron Foundry)
Unaccounted difference	1,748 days per 1,000 men or 8,741 days per 5,000 men	

Since this difference of 8,150 days can be accounted for in most part by the failure to include 1 and 2 day disabilities in the statistics, it is quite fair to distribute them in the same way as are the 3 day disabilities, namely:

Respiratory (inc. N. & T.).....	53% or 4,633 days per year
Gastrointestinal	9% or 787 " " "
Non-Industrial Accidents	3% or 262 " " "
Industrial Accidents	0% or 0 " " "
Non-Resp. Non-Digestive	35% or 3,059 " " "

not kept a record of disabilities of 2 days or less, and (2) our method of discovering disabilities of 3 to 7 days in length have been faulty due to the uneven and sometimes short work week. Also when employees discover that their disabilities are being recorded they occasionally give a false reason for their absence. You will note that the unaccounted difference in days lost per 1,000 per year is 1,748, which closely approximates the 1,595.3 days per 1,000 which Dr. Gafafer found that his group lost during the first 2 days of disability. We thought we were doing a good job but this comparison suggests that our failure to record disabilities of 2 days or less means a statistical loss of at least 23 per cent of the total days lost by industrial workers. It may be that this 23 per cent will prove to be of vast importance in determining the healthiness

or otherwise of an industry. In this group of 5,000 foundry employees, the failure to keep records of disabilities of 2 days or less, when compared with Dr. Gafafer's group, means that 8,741 days per year at least are unrecorded. I will show that this figure is probably greater. When this is broken down into broad causative groups of respiratory, gastrointestinal, non-respiratory, non-digestive and accidents, the results are more significant. If in a foundry where the study of respiratory diseases is so important we are failing to record 4,633 days of disability per year due to respiratory diseases occurring in a group of 5,000 it would seem to be a serious statistical loss. It may be important to determine where in the foundry these 4,633 days of disability were distributed.

So far I have assumed that foundry

work is as healthful as in a public utility, and that we have been able to record most disabilities of 3 to 7 days' duration. But if we assume that there is a proportion between the number of disabilities lasting more than 7 days and those lasting 7 days or less, then we would have to revise our figures. If we are fair in making this assumption, then the 195 disabilities per 1,000 of 3 to 7 days in length occurring in our foundry would become 462 per 1,000 to correspond with Dr. Gafafer's findings of 390.1 per 1,000 disabilities of 3 to 7 days in length, and 153.1 per

1,000 of 8 days or more. Carrying this analogy further it is found that we should expect 419 disabilities per 1,000 (2,095 disabilities among 5,000 men) lasting 2 days or less in our foundry, and if this all be true the importance of recording these short disabilities is all the more evident since our estimated difference of 8,741 days lost per 5,000 men per year during the first 2 days of disability becomes an estimated 9,803 days per year which we have failed to record by not listing disabilities of 2 days or less.

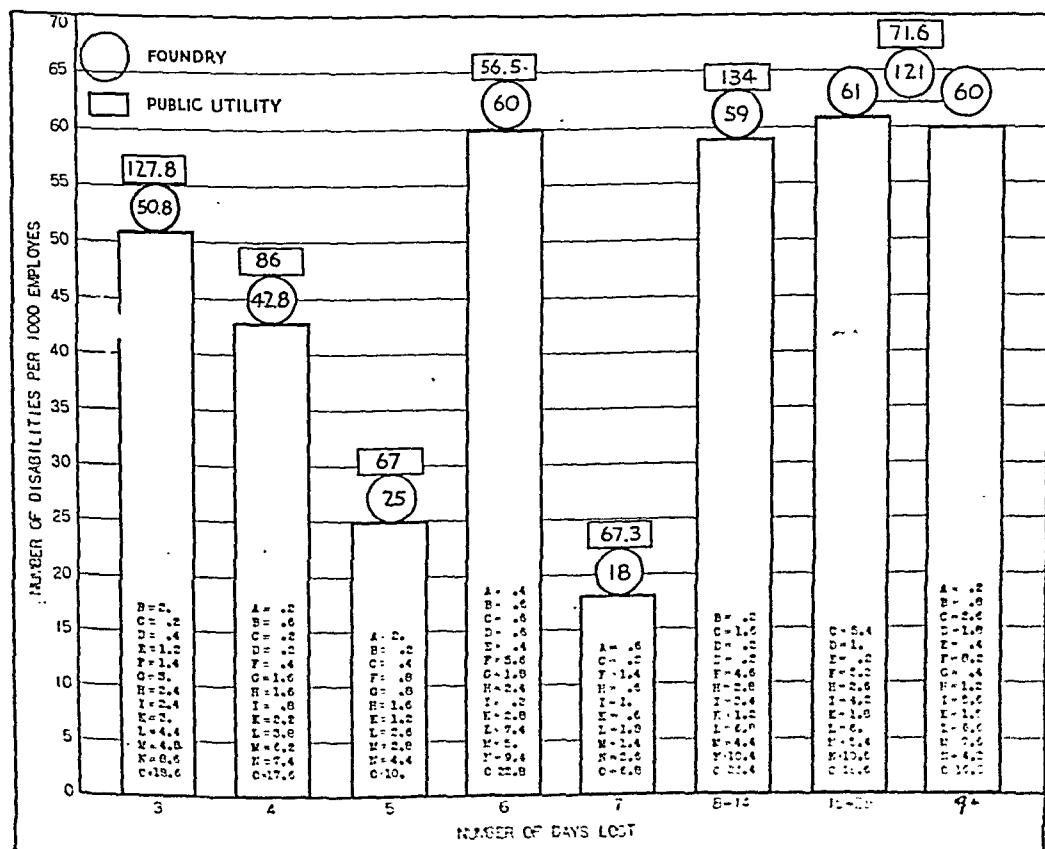

Table II is shown to display in more

TABLE II

NUMBER OF ABSENCES PER THOUSAND EMPLOYEES BY LENGTH OF DISABILITY AND CAUSE

A=Ind. Acc. B=Heat & Cold
C=Contagious Diseases D=Cardio Vascular E=Cerebro Spinal
F=Accidents - Non-Industrial
G=Dental H=Skin I=Genito Urinary K=Miscellaneous
L=Joints M=G.I. N=X.E.N.&T
O=Respiratory (Results if not noted are zero)

TOTAL NUMBER OF DISABILITIES	1877	PER M. 377
NUMBER LOSING 7 DAYS OR LESS (1 and 2 day disabilities not counted)	986	193
NUMBER LOSING 8 DAYS OR MORE	891	178

graphic form the difficulties encountered in recording short term disabilities where there is neither incentive nor necessity for employees to report them exactly. You saw that Dr. Gafafer's curve of the annual number of absences per 1,000 persons is more or less definitely parabolic whereas the curve for our industry where a real effort has been made to record all disabilities of 3 days or more is found to be absolutely irregular. This is best seen in the unexpected drops in the number of 5 and 7 day disabilities. This might be explained by the tendency on the part of employees to consider a week to be 6 days, omitting Sunday, or where the work week was 4 days to consider oneself to be disabled 4 days instead of 5. And so without an adequate incentive such as payment of benefits for every day of disability it would seem impossible to arrive at an accu-

rate figure of the days lost per 1,000 per year, during the early periods of disabilities. In this table for sake of completeness I have included under each group of disabilities the various causes of these disabilities. Dr. Gafafer's group lost $7\frac{1}{2}$ days per man per year, whereas our foundry group is charged with but 5.8 days per man per year and we thought we had recorded most disabilities of 3 days or more. No one figure can more adequately express the need of recording those earliest days of disability and particularly the first and second days.

Dr. Gafafer has thrown open the doors to a field of industrial medical research which may prove of vast importance in the determination of industrial health. Years of study of this problem will be necessary before the answers to many questions which now present themselves can be obtained.

THE ORAL HEALTH GROUP

ANNOUCEMENT was made in the *Journal* shortly after the meeting of the Association in New York in 1937 regarding the formation within the Association of the Oral Health Group. This informal association had among its objectives the fostering of an interest in dental matters throughout the various Sections. The first year's activities of this group culminated in the appearance of several notable papers on dental problems at Kansas City, a successful Oral Health luncheon, and the presentation of a symposium on "How to Improve Dental Health in the United States," jointly sponsored by the Public Health Education and the Child Hygiene Sections.

Three of the papers read in the symposium appear in this issue. They present points of view which should engage the attention of all who come in contact, as what public worker does not, with dental disease in any of its various manifestations. When one considers the undoubted deleterious influence of dental infection on general health, the progressive nature of dental disease when neglected, and its practically universal incidence, it is only natural that this subject should receive increased attention.

Professor Turner's paper outlines an effective approach to the community dental program through health education. Dr. Cady gives major consideration to the dental service problem. Dean Millberry's paper makes a direct approach to the economic problem involved in providing dental care and deals with two of the outstanding items contributing to the cost of dental service, the cost of dental equipment and the cost of dental education. Believing that dental equipment, practicable at least for children's dental care, can be manufactured through mass production methods at much less than current prices, he proposes also the reduction of cost of dental education through a curtailed course of instruction designed to prepare dental practitioners trained to give preventive and corrective dental care to children only, under the jurisdiction of the health department or board of education. The course would consist of two years of

predental college work and two years of training in the dental school. This is a somewhat revolutionary concept and demands careful consideration, especially as it has not had a hearing before either the American Dental Association or the American Association of Dental Schools.

Dean Millberry's plan was based on a program proposed by him at the University of California in 1925, adopted by the Academic Senate, and approved by the Board of Regents. Basically, it provided for the education of persons who would pursue professional studies for four years after completing high school, at which time a Bachelor of Science in Dentistry would be awarded. Millberry believes that such persons would be qualified to perform the simpler types of dental operations which constitute about 80 per cent of the practice of the average dentist. Some of these students might go on with further studies to be recognized with higher degrees. When proposed in California, dentists who felt that the Doctor's degree in Dentistry was a requisite for practice protested violently, and the plan was abandoned.

Dean Millberry calls attention to the fact that in New Zealand a similar type of training has been given to young women after two years of dental training only, with no prerequisite college work, and who serve the children in the public schools. He claims that even with this shorter period of study the program is successful and that it is so regarded by the dentists in New Zealand.

The dentist members at Kansas City took issue with Dean Millberry's proposal, believing that dental disease in American children is becoming more complex in its manifestations and that, in consequence, operators could not be trained in two years in the dental school to cope with the diagnostic and operative problems involved. Attention was also called to the dangers under such a plan of illegal practice by those licensed to practise in a restricted field. Altogether, they felt that it would be quite unacceptable to the American Dental Association and to dentists generally throughout the country.

There can be no doubt that the cost of dental treatment is high and that the funds for providing it on a community basis are all too small. Any relief, such as that offered by Millberry, will seem welcome to public health administrators, most of whom have little knowledge of the technical problems involved. Over against this group will be the mass of dentists who will probably prejudice this proposal on its departure from the *status quo* without inquiry into its possibilities. Without taking a stand for or against the Millberry plan, it at least seems proper to suggest its consideration by a group of dentists thoroughly familiar with the problems involved in giving dental care to American children. A critical evaluation of the New Zealand method seems desirable also, particularly with regard to its applicability to North America.

An important consideration is the ultimate effect which such a project would have on the standards of dental practice. Would it be in the public interest to endorse a scheme which would make dental or medical practice less attractive to our best qualified men and women and thus bring into the professions a group having inferior qualifications?

There is a more fundamental need than that which Dean Millberry's plan is intended to meet, namely, the need for reducing dental disease which is so much on the increase and which even now calls for so vast an amount of treatment services. Even the savings which are envisioned in the Millberry plan would hardly make possible the control of all the dental caries known to

exist in the mouths of the nation's children. Even more than the financial relief which Dean Millberry would afford us, we need a broad and inclusive research to determine how dental decay can be prevented and a dental health education program which will put the findings of that research to work. These aims would seem readily attainable and thoroughly practical, and should be effectuated as early as possible in order that the nation may promptly benefit from the services now enjoyed only by the few.

PROFESSIONAL LEADERSHIP IN THE SCHOOL HEALTH PROGRAM

THERE can be no doubt that school health programs are ready to share in the expansion that is now affecting all public health enterprises. It has been said that leaders arise in response to needs. Where shall we find the leadership to advance this important phase of health work? How can the American Public Health Association assist in its development?

Competent professional leaders, capable of investing school health work with a sound philosophy and of giving it practical direction, are not wanting in the American Public Health Association but they are scattered through many of the Association's Sections. This is only natural because a variety of special interests is inherent in school health programs. What Association facility can implement the needed leadership?

It was with such questions in mind that representatives of the American School Health Association met with the Section Council of the Child Hygiene Section of the A.P.H.A. at the Kansas City Meeting, and proposed that the two associations join hands in an effort to mobilize their findings for the guidance of those in school health work.

Members of the Child Hygiene Section recognize that the scientific sessions in which the American School Health Association has participated have already served to unite many special groups in the interest of better school health programs. The Child Hygiene Section has a continuing concern with the child of school age, but accepts the American School Health Association as an agency specially focused on school health program policies, procedures and organization.

Believing that we should achieve some formal recognition of an informal relationship that has extended now over twelve years, a movement is under way which will place the American School Health Association in the position of an associated organization of the American Public Health Association. Such a plan has been approved in principle by the Committee on Constitution and By-laws of the A.P.H.A., and the Executive Board has authorized that this suggestion be brought to the attention of the Governing Council of the next Annual Meeting in the belief that some such recognition should be approved.

The key to the solution of school health problems lies in teamwork between the professions of education and public health. On the side of the educator developments have been rapid since June, 1937, when the American Association for Health, Physical Education and Recreation was organized as a department of the National Education Association. In November, 1938, a conference was held in New York City which was attended by many agencies with interests in the health education approach through the schools, and the A.P.H.A. has

accepted membership on the Board which will undertake the coördination of these programs between health and educational groups. Professor Ira V. Hiscock of the Yale Medical School has been designated as the Association representative.

Confidence in the belief that a good foundation has been laid for coöperative understanding in this field, and that special interests must give way to coöperative action, the future of these relationships seems encouragingly clear.

LIABILITY FOR WATER-BORNE DISEASE

IT is now a well established principle of law that a purveyor of water for human consumption, whether a private water company or a municipal corporation, will be liable for damages to consumers who contract diseases from the water as a direct result of negligence on the part of the purveyor.¹ While not an insurer or guarantor of the purity and potability of the water, a municipal or private corporation has the duty of ascertaining the quality of its water supply, and it must take all necessary precautions to safeguard the health and welfare of those who use the water. Failure to discharge this responsibility creates a legal wrong.

In view of the numerous outbreaks of water-borne disease that have occurred in this country and abroad, and in view of the many court decisions upholding awards of substantial money damages to persons injured by contaminated water, this legal doctrine ought to be familiar to all water works officials. Too many public and private vendors of domestic water supplies seem unable, however, to learn the bitter lesson of experience.

In 1878, for example, there occurred at Caterham and Redhill in England an epidemic of typhoid fever, caused by pollution of a public well by a workman who was a carrier of typhoid fever.² Here was a salutary lesson, and yet 60 years later history repeated itself.

Late in 1937 and in 1938 Croydon, England, was visited by a disastrous epidemic of typhoid fever, upon which we commented editorially last May.³ According to more recent reports in British medical publications,⁴ this preventable outbreak was responsible for 322 primary and 19 secondary cases of typhoid, with 43 deaths. This unnecessary slaughter was due to contamination of a public well by a workman who was a typhoid carrier.

Since the corporation had negligently omitted the customary filtration and chlorination of the water supply while the workmen were engaged in their operations, this London suburb is reported as now being confronted with claims for damages for this epidemic amounting to more than £100,000, or nearly half a million dollars. Carelessness in community health protection apparently does not pay.

In a lawsuit brought against the corporation by a father whose daughter suffered a dangerous illness in this outbreak, an award of £400 damages is said to have been made by the English High Court. The corporation, apparently realizing the hopelessness of reversing this decision, is reported as having decided not to appeal.

The court made its adjudication mainly on the matter of negligence. Since the father and not the daughter had a contractual relationship with the corporation under existing statutes, there was no breach of warranty in the case of

the daughter. There was, however, the right of redress at common law for negligence, and this was adequate to justify the award upon proof of the fault of the corporation.

The American courts have taken the same position in a long line of decisions.⁵ In 1928, for instance, an award of \$2,000 to a minor and \$1,000 to his father was sustained by the highest court in New York in a case where typhoid fever had been contracted from a city water supply which had been contaminated by sewage from an old canal.⁶

Despite unfortunate experiences such as this, an epidemic of water-borne typhoid occurred in Olean, N. Y., in 1928, and resulted in the payment of claims by the city amounting to more than \$400,000.⁷ We repeat that negligence in performing an important public health duty, such as the maintenance of the purity of a domestic water supply, is a costly mistake.

Sanitarians, municipal authorities, and water works officials should take keen cognizance of their legal responsibilities, and should carefully consider the legal liabilities of public and private corporations in performing such proprietary functions as dispensing water and disposing of sewage. Prevention of disease in such instances not only is a necessary humanitarian duty, but it is an economic safeguard of vast significance. The maxim that ignorance of the law is no excuse is not yet obsolete.

EDUCATING FUTURE ENGINEERS

IN a recent issue of the *Public Health Reports*, there appeared an article summarizing the results of a study of 4 year undergraduate college courses available during the academic year of 1936-1937 for students wishing to follow sanitary engineering work or engage in public health engineering activities. Under six main divisions and fifty sub-divisions, the curricula of twenty-six courses in sanitary or public health engineering were broken down so as to show the per cent of time allotted to the subject matter described by the sub-division titles. Two of the main divisions were sanitary engineering and public health. Some of the material in this article merits more analysis than was given to it, even though such a study results only in the statement of certain questions for which answers are not immediately forthcoming.

Using sanitary engineering and public health subjects as a yardstick, the figures in one table show that the percentage of time allotted to these two broad classifications range from 24.8 to 4.6 of the total, and, if the highest figure is excluded as not being entirely comparable to the others because it pertains to a course definitely designed for public health engineering training, the range is from 20.4 to 4.6. The average time-allotted figure for these lower twenty-five

courses is 11.3 and fifteen courses are found to devote lesser amounts of time to the two subjects under consideration than this average. In the case of two colleges, their courses include less time on these important subjects than is devoted to the same studies—on the average—by forty-five colleges which make no pretense of offering training for work in this field. If a generous allowance is made for differences of opinion as to what should be included in such courses, it would seem that this spread in the time-allotted figures is too great and that some of the courses are not providing the material to the students which the future field of activity demands.

Is there need for a sharper line of demarcation between training courses for the undergraduate sanitary engineer—the designer, builder, seller, and operator of sanitary works—and the public health engineer—the designer, builder and seller of public health engineering? If so, there is likewise need for more and better educational opportunities for those wishing to confine their life work to the public service of health improvement and protection. On the other hand, should the engineer first be trained in basic engineering knowledge and then have superimposed on that additional work emphasizing public health as a specialty? Neither of these questions can be answered today, but if both sanitary and public health engineering graduates are to go into the field of public service after only 4 years of undergraduate work, there is need for many curricula to be recast in the light of the present scope of environmental sanitation work.

PUBLIC HEALTH EDUCATION*

How to Write Badly—By Our Own Cliché Expert. "Being in a cynical mood this afternoon," writes our Cliché Expert from Boston, "I have to disgorge myself of something that has been eating at my vitals for some time."

A hurried review of the season's morbidity reports should be termed "an intensive epidemiologic study."

Any health project that is undertaken in three or more communities becomes known as "a nation-wide campaign"; or, a-la-Kipling, "far flung."

If some prominent people are met in the day's work, be sure to report that "the key people were contacted"—thus killing two (cliché) birds with one stone, if we may coin a phrase here.

A brief publicity project may be cursed effectively by having it designated a "drive" or better an "intensive educational campaign."

If a committee is asked to meet, do not fail to extoll the virtues of "group thinking": it makes for clarity when a verb is tortured to create a doubtful noun.

When the help of others is needed, it must be emphasized that nothing short of "100% coöperation will do." Another convincing expression is "about 75%," for the symbol of an exact determination qualified by an approximation becomes pleasantly obscure.

No scientific paper is complete without some reference to the "average man," or "normal health," however meaningless the expressions may prove.

Scientific jargon impresses the lay reader even if he does not understand it, so use "optional nutritional status," "case fatality rates," or "upper respiratory infection," whenever simpler terms would do.

Who Wrote This Letter?—Many letters leave a bad taste because the signature is hard to read. You may have noted a new style in business let-

ters, which has been urged by *The Reporter*, 17 E. 42nd St., New York, N. Y. In place of the double set of initials at the lower left corner of the letter, the full name of the dictator appears, such as,

Henry E. Smith:MBS

Others who wish to increase signature readability and acceptability may well take up the long accepted but not always used fashion, having the full name typewritten below the pen written signature.

Anyway let's take the puzzle out of the signature.

Why Not Two Copies?—A subscriber to *The Reporter*, direct mail advertising journal, wishes that the magazine was printed on one side of the page for clipping and filing.

A better plan would be to subscribe for two copies. Files of magazines have serious limitations for reference use. Two copies of the *Journal* would enable a health agency to cut freely and file articles which would make up a splendid reference collection.

Add two copies of *Hygeia* for popular material, and the health educator would have an unexcelled reference library.

March of Health Broadcasts in Illinois—From Radio Speaker Leona de Mare East, Illinois Department of Public Health, we have this helpful outline of procedure:

The topics of the weekly broadcasts are selected from 13 to 26 weeks in advance by the Division of Public Health Instruction. The educational material is interwoven into as dramatic a 15-minute radio play as possible by the staff radio speaker. Each play is

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22nd St., New York, N. Y.

approved in the Instruction Division and mimeographed. Before being produced it is checked by staff physicians, nurses, engineers, or bacteriologists, according to the field in which the subject falls. The aim is to present accurate and stimulating health information in a form that has enough listener-interest to compete with commercial radio shows. Actors with professional experience are recruited both from the department's staff and from local dramatic groups. The electrical recordings are produced in a commercial studio under the direction of the author. From the original master transcription 18 copies are made for shipment to the 18 cooperating radio stations. This gives the Department a total of $4\frac{1}{2}$ hours of air time a week, covering the rural as well as the urban areas of the state. A gratifying response has followed the occasional offers of health pamphlets on these broadcasts.

The station schedule appeared in *Illinois Health Messenger*, Springfield, for Dec. 1, 1938. Miss East will supply copies of the broadcasts, and will welcome suggestions or criticisms.

Making It Easy for Visitors—
The Altro Workshops, conducted by the Committee for Care of Jewish Tuberculous, 71 West 47th Street, New York, N. Y., is located in a faraway spot unfamiliar to most of those who would attend even a 25th anniversary. So with the invitations was enclosed a slip $3\frac{1}{2} \times 5\frac{1}{2}$ inches which is reproduced on this page. Probably other agencies have used a simple map to encourage visitors, for a special occasion or throughout the year. A few social agencies use interesting picture maps.

"Make a Note of It"—This title of a plea for note-taking is developed in *Rotarian*, 35 E. Wacker Drive, Chicago, Ill. Jan., 1939. 25 cents.

It tells why we should make more of an effort to tie down fugitive thoughts and observations, what we read and

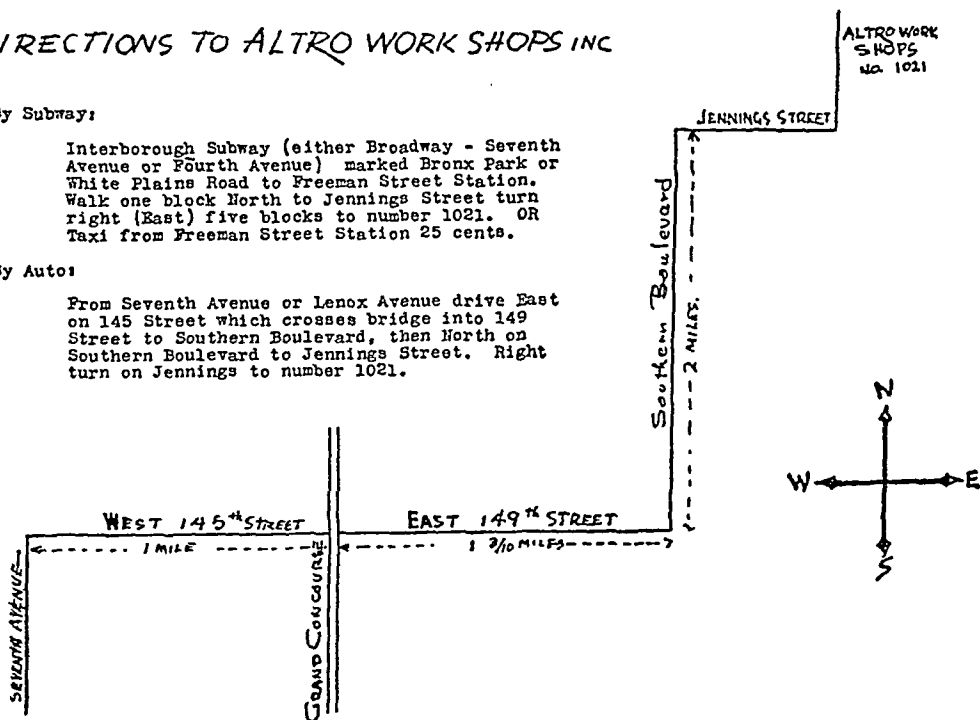

DIRECTIONS TO ALTRO WORK SHOPS INC

By Subway:

Interborough Subway (either Broadway - Seventh Avenue or Fourth Avenue) marked Bronx Park or White Plains Road to Freeman Street Station. Walk one block North to Jennings Street turn right (East) five blocks to number 1021. OR Taxi from Freeman Street Station 25 cents.

By Auto:

From Seventh Avenue or Lenox Avenue drive East on 145 Street which crosses bridge into 149 Street to Southern Boulevard, then North on Southern Boulevard to Jennings Street. Right turn on Jennings to number 1021.

what we see. Darwin, Edwards, Stevenson, and others testify.

One application:

Try keeping a pad handy to record unusual or half-forgotten words you meet during the course of the day—not necessarily big or out-of-the-way words, but words that strike you as having tang in some connection. It is a simple matter to run over the list at night, and with a decent filing system it is possible not merely to enlarge your vocabulary, but also to add considerably to the interest of your talk and thinking.

A Safety Education Workshop—Ben W. Miller, Director of Driver Research, Indiana University, Bloomington, reports on a Safety Education Workshop in the Student Building:

This Safety Education Workshop was set up in early spring to accommodate our undergraduate and graduate students who are enrolled in Health and Physical Education courses. In it, we had more than 600 different pieces of materials on display, and available for use were twenty $3\frac{1}{2} \times 12$ tables. We had posters on all phases of health and safety on display, and also displayed anatomical charts and models, and other teaching materials, such as the marihuana weed and testing devices. Our materials in Safety Education were grouped according to 4 major headings: Recreational; Transportation; Occupational; and Home and School. This Workshop was used for our elementary teacher training group, our major students in Health and Physical Education, and for all of our graduate students, including special seminars in health and safety. It proved to be quite a popular gathering place for students, and it met with such success that we have asked for special appropriations in our budget to add to the facilities and materials we already have. Another feature of the past summer was the use of this Workshop by the 90 recruits who were being trained by the Indiana State Police. They completed special requirements in the classroom as well as on the road in traffic safety.

Publication by Microfilm—A new medium for the distribution of scientific material is made practicable through University Microfilms, 313 N. 1st St., Ann Arbor, Mich.

Briefly a monograph or dissertation will be photographed from typewritten

manuscript on microfilm. Prints will be supplied at $1\frac{1}{4}$ cents a page. Reading machines are now available in many universities and elsewhere, and low cost machines are near at hand. The service is available to those possessing a doctorate degree or those having a doctorate dissertation for publication. Those interested will receive much additional information upon request.

Wholesale Discussion in Pittsburgh—In October, 1938, the National Recreation Congress (315 4th Ave., New York, N. Y.) included 5 simultaneous discussion groups every afternoon.

Long in advance a 22 page pamphlet, "Topics for Group Discussion," was distributed to the expected delegates.

This pamphlet was made up of 24 sets of questions, one set for each of the discussion periods. We quote the questions under "The Interpretation—A Clinic on Written Reports":

1. What are the criteria by which a report should be judged? (i.e. What makes a report "good"?)
 - (a) What are the physical features that need to be considered, size, paper, etc.?
 - (b) How does the date of publication affect its value?
 - (c) What are the major topics to be considered?
 - (d) How does the length of a report affect its best use?
 - (e) What statistical material should go in and in what form?
 - (f) How can illustrative material be best used? etc., etc.
2. For what constituency is an annual report prepared? How far can it be used to interpret recreation to the public? To what extent does the constituency affect the form and content of the report?
3. How can the annual report data be best related to data of previous years to interpret trends and growth, and how can they be used to forecast future progress?
4. What determines the number of reports to be prepared? How plan for the wisest distribution of reports?
5. What methods have been used to have newspapers use report material affectively?

6. Through what other agencies can the factual material be released to the public in attractive form?
7. What would be the values of establishing national standards for reporting recreation? If desirable, how should it be done?
8. What effect does the popularity of picture magazines have on reporting with photos rather than words?

To make sure that every delegate had an opportunity to present what was on his mind a session on the closing day was devoted to a "Pet Show—A Free for All Exchange of New and Pet Ideas."

Here is a chance for anyone to speak on any topic bearing on any phase of recreation. Parade your pet idea for the benefit of others. Receive new ideas yourself. Speak frankly—state it briefly.

What new ideas have you developed?

What original experiments have been made in your city? With what success?

In what part of your program do you take greatest pride?

If you had unlimited funds, what are the first three things you would do to serve the recreation needs of your city?

What seemingly desirable steps have you tried without success?

This use of discussion was not experimental. For years the National Recreation Congress has been notable for giving considerable time to open discussion. Thus a wealth of practical experience has been made accessible to all. Moreover, careless thinking and half-baked ideas have been brought out into the open.

May there be generous time allotment for discussion when the A.P.H.A. meets in Pittsburgh in 1939.

NEW

Our Children's Health, mimeographed bulletin of 22 pages, issued by Division of Public Health Training, New York City Department of Health. For school physicians and nurses.

TO HELP OR BE HELPED

The Health League of Canada (105 Bond St., Toronto) wants a slogan. To

start your thinking, here are samples:

"Health for all is wealth for all" . . .
 "Health for all and all for health" . . .
 "Happy he who holds his health" . . . "Put on the armor of health."

"There's Nothing Wrong With Your Mind!" That is, if "you can't make it work" and make it "stick to the subject," according to H. D. Kitson, Ph.D. For the normal minded who don't think enough or think hard enough. *American Journal of Nursing*, 50 W. 50th St., New York, N. Y. Feb., 1939. 35 cents.

MIMEOGRAPH OR PRINT

If you wish to consider a variety of folds in a novel announcement or invitation . . . or if you are interested in the pleasing effects of a white paper with one side tinted . . . ask Appleton Coated Paper Co., Appleton, Wis., to send portfolio of samples of "dull-chrome" paper, and tell you where to buy it.

Ready-made illustrations for inserting, as is, and quite simply, in the stencil which has been typewritten with space left for the illustration, are provided by Milo Harding Co., 613 Commonwealth Annex, Pittsburgh, Pa. An instruction sheet, and proof sheets at intervals, will be sent upon request. You order the sheet you want, and when you want it. This service makes it possible to use timely illustrations in any bulletin or other mimeographed job. If you don't fully understand the idea, please write the Editor.

MOTION PICTURES

The National Tuberculosis Association has recently released "On the Firing Line." In sound on 16mm. and 35mm.

Accompanied by crisp, running narrative, the film takes the audience to various points of interest including Trudeau Sanatorium, Waverly Hills Sanatorium, the bayou country in Louisiana, the University of Minne-

sota, and the southwest. There are scenes showing the public health nurse on her rounds, the research laboratory, industrial workers, Negroes, and so on. Animated isotype graphs (picture diagrams produced by Dr. Neurath) present the statistical facts.

MAGAZINE ARTICLES

"Sulfanilamide," by J. Pfeiffer. *Harpers*, 49 E. 33rd St., New York, N. Y. March, 1939. 40 cents. "The story of a great discovery."

"Sleep and Insomnia," by G. W. Gray. *Harpers*. Nov., 1938. First of a new series of medical articles.

DATES AHEAD

Early Diagnosis Campaign, April 1-30. See any tuberculosis association.

Silver Anniversary Observance of National Negro Health Week, April 1-30, 1939. Address: National Negro Health Week Committee, U. S. Public Health Service, Washington, D. C. The "Week" is April 2-9, but the Anniversary will extend through all of April. Ask for samples of history and plan bulletin, poster, and school poster, and information about the poster contest and the awards for successful local observance of the event.

"Boys and Girls Week," April 29-May 6, includes "Health Day," May 1. Address: National Boys and Girls

Week Committee, Room 950, 35 E. Wacker Drive, Chicago, Ill.

"May Day—Child Health Day," May 1. Slogan: "The Health of the child is the power of the nation." Address: U. S. Children's Bureau, or your own State Committee. Children's Bureau has issued a new May Day poster, 30 x 34 inches. 20 cents. Quantity discounts. Order from Superintendent of Documents, Washington, D. C. Write the Bureau for new series of May Day leaflets.

"National Hospital Day," May 12, 1939. Address: Albert G. Hahn, Chairman, National Hospital Day, Deaconess Hospital, Evansville, Ind. Also, Physicians' Record Co., 161 W. Harrison St., Chicago, Ill. See plans for the day under "Public Education" in "Hospital Organization and Management," by Dr. M. T. MacEachern.

Both the San Francisco and New York expositions have announced May 12 as "Hospital Day."

Annual Meeting of National Tuberculosis Assn., Boston, June 26-29, will include health education topics.

Interpreting Modern Methods of Tuberculosis Control to the Public . . . Negro Health Education . . . Tools of Health Education (including printed word, visual education, spoken word) . . . Junior High School Health Education . . . Public Relations (in National Conference of Tuberculosis Secretaries).

BOOKS AND REPORTS

Books of Special Interest to Public Health Workers

MAZÏCK P. RAVENEL, M.D.

"Of making many books there is no end; and much study is a weariness of the flesh." So saith The Preacher, so we are here making an attempt to lighten the burden of our readers in this respect.

An interesting function of the Editorial Office is the examination of new books and a report of them to our readers. We limit our published reviews almost entirely to those which are devoted to the consideration of matters treating directly of any of the various concerns of public health and personal hygiene, though a considerable number of other books are gone over.

It has seemed helpful at the end of each year to scan the reviews published in our own *Journal* as well as a number of others, and select from them those which we believe to have special interest and usefulness to the constantly increasing numbers engaging in the many fields of public health who do not have access to the large number of new publications, copies of which the publishers are courteous enough to furnish to us.

As has been our custom in the past, we depend most on the reviews in our own *Journal*, but consult a number of others, chiefly the *Journal of the American Medical Association*, the *British Medical Journal*, and *The Lancet*. The brief opinions expressed are taken from the original reviews, often in the exact words, though quotation marks are not used.

Publishers have shown as much interest in our endeavor as our readers

have, and to them we express our appreciation of their liberality and courtesy.

This year we include only books of which the reviews have appeared during the nine months of 1938, May to December, inclusive.

CHILD HYGIENE

As usual, for a number of years past child hygiene has received a great deal of attention, but again, while there have been a number of articles, not many books on the subject have come to hand. *The Compleat Pediatrician: Practical, Diagnostic, Therapeutic and Preventive Pediatrics*, by Wilbur C. Davidson, Duke University Press, 2nd rewritten edition, is a valuable compendium of pediatric materials prepared as a ready reference for practitioners of medicine especially interested in pediatrics. *Modern Ways With Babies*, by Elizabeth B. Hurlock, Lippincott, is readable and comprehensive and is an excellent common sense aid to the intelligent mother.

HEALTH EDUCATION

There is growing interest in the matter of health education, especially in the early years. In addition to various reports and discussions, the following books seem to be of especial interest: *How To Be a Convincing Talker*, 2 vols., by J. George Frederick, Business Bureau, is recommended by the reviewer as "usable by many *Journal* readers." It is a valuable exposition of the im-

portance of good language and of public speaking. *Integration, Its Meaning and Application*, by L. Thomas Hopkins and others, Appleton-Century, is an excellent and interesting volume for those engaged in health education.

HISTORY AND AUTOBIOGRAPHY

There is a distinct trend on the part of physicians to write histories of all kinds. Several excellent autobiographies have appeared which are interesting not only as lives of the individuals concerned, but especially so because they tell much of the medical customs and practices of their times. Perhaps the most popular of these is *The Horse and Buggy Doctor*, by Arthur E. Hertzler, Harpers, which is a best seller. *More of My Life*, by Andrea Majocchi, Knight Publishers, is a fitting sequence to *Life and Death*. Among the many autobiographies by doctors which have appeared during the last few years, this stands easily at the top. It is a human document of intense interest. *Fifty Years a Country Doctor*, by William N. Macartney, Dutton, is a most interesting autobiographical volume which boosts the country doctor and holds that he is not only important to the world but will continue to maintain his place. *Not So Long Ago—A Chronicle of Medicine and Doctors in Colonial Philadelphia*, by Cecil K. Drinker, Oxford University Press, is a contribution to colonial history as well as to medical history of that period which has excited approbation everywhere. It concerns particularly Philadelphia and Pennsylvania. *Public Health and Medical Licensure in the State of Mississippi, 1798-1937*, by Felix J. Underwood and R. N. Whitfield, Mississippi State Board of Health, is excellent as history and as an example. *The Conquest of Cholera, America's Greatest Scourge*, by J. S. Chambers, Macmillan, is a most interesting and valuable account of

cholera in the United States from its first appearance (1832) and its conquest in 1892. *Milestones in Medicine*, Introduction by James Alexander Miller, Appleton-Century, is made up of the "laity lectures of the New York Academy of Medicine" and is excellent as helping the public to understand the medical profession.

INDUSTRIAL HYGIENE

There have been innumerable articles and reports on industrial hygiene. There is constant increase in the number of chemicals and processes entering into manufacture and the industrial occupations, but few books have come to our notice. *Toxicology*, by William D. McNally, Industrial Medicine, a book of more than 1,000 pages, is a leader in industrial toxicological field and is indispensable to those interested in toxicology and its medicolegal aspects. *Fluorine Intoxication*, by Kaj Roholm, H. K. Lewis and Co. Ltd., is especially recommended for those interested in any of the various phases of fluorine intoxication. *Third Symposium on Silicosis (Saranac Lake)*, edited by B. E. Kuechle, Employers' Mutual Liability Insurance Co., is the third annual symposium by noted students of this most important disease, which still presents many problems. There is nothing better of its kind in existence. *Carbon Monoxide Asphyxia*, by Cecil K. Drinker, Oxford Medical Publications, is a comprehensive and critical review by an authority of long experience. *Occupation and Health*, Supplement, International Labour Office (U. S. Branch, Washington) is written by outstanding authorities, mostly European. It is appearing in the form of brochures, 16 of which were issued in 1938. Highly valuable. From the same source comes *Workmen's Compensation for Silicosis*, giving summaries of the legal phases of the question throughout the world. These

supplement the Symposium from Saranac. Available in this country in 1938 though issued in 1937, is *Toxicology of Industrial Solvents*, compiled by the Industrial Research Board of the Medical Research Council of England, H. M. Stationery Office, which is indispensable to all working in this field. Closely related to the problems of the industrial hygienist are *Medical Jurisprudence and Toxicology*, by John Glaister, of which the 5th Edition was issued by Wood during the year, and *Medical and Legal Aspects of Tuberculosis as an Occupational Disease and as an Industrial Injury*, by Mary Graham Mack, National Tuberculosis Association.

LABORATORY

Outstanding among strictly laboratory books are *The Laboratory Diagnosis of Syphilis*, by Harry Eagle, Mosby. This is a very valuable study of a matter of vast importance which will command the respect of all readers. *A Textbook of Hematology*, by William Magner, Blakiston, is an excellent book which merits a high degree of popularity among technicians and practitioners of medicine. Among new editions is the second edition of *Approved Laboratory Technic*, by John Kolmer and Fred Boener, Appleton-Century. This is a well known textbook with 28 collaborators, the first edition of which was well received.

Bacteriology is the foundation of modern public health practices. Parasitology refers to animal parasites and for many years a section on this subject has been included in all textbooks on bacteriology. Consequently we look forward with a great deal of interest to all new books on these subjects. Perhaps the most notable publication of the year has been *The Biology of Pneumococcus*, by Benjamin White, et al., Commonwealth Fund. Giving an extensive bibliography, it is an excel-

lent reference book and readable. In the death of the senior author since this book appeared, the scientific world has suffered a great loss. We know of no study of the pneumococcus in this country which is more complete than this, beginning with the discovery of the germ in 1875. Another outstanding book is *Parasitology: With Special Reference to Man and Domesticated Animals*, by Robert Hegner, Francis M. Root, Donald L. Augustine, and Clay G. Huff, Appleton-Century. Special emphasis is laid on parasites which affect man—one of the best text and reference books in the English language. The second edition of *Bacteriological Atlas*, by Richard Muir, Wood, has been issued. It contains a number of improvements over the first edition, though still ultraconservative as far as nomenclature goes, and is an excellent work. *Dairy Bacteriology*, by B. W. Hammer, Wiley, is a notable second edition of a book which is one of the most authoritative and useful in its field. *A Textbook of General Bacteriology*, by Edwin O. Jordan—Revised by William Burrows, Saunders, is a standard text of many years. The revision is not all that could have been wished, but the book is still standard. *Pneumonia and Serum Therapy*, by Frederick T. Lord and Roderick Heffron, Commonwealth Fund, is the last word on serum therapy of pneumonia and is invaluable to practitioners and health officers. *Bacteriological Metabolism*, by Marjory Stephenson, Longmans. This is a second edition just out in 1938, and is perhaps the best thing on the subject, for general use, at any rate.

MENTAL HYGIENE

During the past year interest in mental hygiene has been very much to the fore. A striking instance was the symposium on mental health at the meeting of the A.A.A.S. Naturally much attention

has been paid to the development of the child along these lines. Among notable books are: *The Psychology of the Unadjusted School Child*, by John J. B. Morgan, Macmillan, a revised edition of a standard book issued in 1924, which is characterized by directness, clarity, and authenticity. It is an excellent practical guide for teachers and parents. *Clinical Psychology: A Handbook of Children's Behavior Problems*, by C. M. Louttit, Harper, is a clear interpretation of carefully collected material and its practical applications. Useful not only to the psychologists but also to medical students or the physician or school administrator seeking to keep abreast of the most recent work in the field of clinical psychology. *The Subnormal Mind*, by Cyril Burt, Oxford University Press, 2nd edition, is a worth while addition to the library of any worker in the broad field of child welfare. *Mental Hygiene for Nurses*, by Elizabeth Lee Vincent, Saunders, has already been mentioned under the heading of Nursing. *Mental Health Through Education*, by W. Carson Ryan, Commonwealth Fund, is of interest to all concerned with the influence of educational programs on the personalities of teachers and pupils and gives added impetus to the movement for a comprehensive, dynamic school program. *Safeguarding Mental Health*, by R. C. McCarthy, Bruce Publishing Co., is a well written book for popular use—parents, teachers, and any others who have to do with training of children. *Child Guidance Procedures: Methods and Techniques Employed at the Institute for Juvenile Research*, Paul B. Schroeder, Director, Appleton-Century, is a notable book which might be put under one of several heads. The dominant idea, however, is child guidance procedures.

NURSING

Public health nursing continues to

hold the interest of all public health workers and, while there have been many discussions, all of them flattering to the part which the public health nurse takes in our social life, few books have appeared. *Personnel Policies in Public Health Nursing*, by Marian G. Randall, Macmillan, should be in the hands of every public health worker. Every chapter is full of meat. *Mental Hygiene for Nurses*, by Elizabeth Lee Vincent, Saunders, is a "must" book for every nursing library. It is a thoroughly excellent and exceedingly useful book. *Jurisprudence for Nurses: Legal Knowledge Bearing Upon Acts and Relationships Involved in the Practice of Nursing*. By Carl Scheffel and Eleanor McGarvah, Lakeside Publishing Co. The second edition of this text has been broadened somewhat to include new material on the legal standards of the nursing profession. *The Hospital Head Nurse*, by Mary Marvin Wayland, meets the great need of those who are particularly concerned with the efficient conduct of the executive aspects of ward nursing and the training of nursing personnel.

NUTRITION

Nutrition continues to hold a high place in the health discussions in every part of the world. Perhaps the vitamins and their influence are more discussed than any other single feature of nutrition, and during the past year the synthesis of vitamins has progressed rapidly and some of them, notably B., have been put on the market for the treatment of disorders of the nerves, arthritis, etc. There has, however, not been a great output of books, though some new editions have appeared. Chief among these is *The Foundations of Nutrition*, by Mary Swartz Rose, Macmillan, 3rd edition, a welcome revision of a widely used textbook of college courses in nutrition. There is none better. As an illustration of the

use of some of the vitamins in medicine we find *Vitamin B₁ (Thiamin) and Its Use in Medicine*, by Robert R. Williams and Tom D. Spies, Macmillan. A valuable contribution to the scientific literature of nutrition and excellent in every respect.

PUBLIC HEALTH ENGINEERING

Manual for Water Works Operators, edited by E. W. Steel, is an excellent exposition of basic information on water works operation, which is a desirable addition to the library of water works departments. *Public Works Engineers' Yearbook, 1938*. Including the Proceedings of the 1937 Public Works Congress held at Atlanta, Ga., October 4-6, 1937, published by the American Public Works Association. In addition to the more detailed discussion of selected problems of current interest to public works officials, this report contains a review and appraisal of events and developments in all phases of public works engineering. *Sanitary Engineering as a Career: A Monograph (from "Careers")*. Published by The Institute for Research Devoted to Vocational Guidance. The profession of sanitary engineering evolved with the discovery that certain microscopic organisms and bacteria are the causes of some of the worst human diseases.

SOCIAL HYGIENE

In our last annual review we gave a section to syphilis. This disease and venereal diseases in general, have been the subject of many articles. Books which have treated of these diseases are often largely sociological and we have classified them this year under social hygiene. *Syphilis, Gonorrhea, and the Public Health*, by Nels A. Nelson and Gladys L. Crain, Macmillan, is written for health officers, physicians, nurses, social workers, and public health workers. It is comprehensive and authoritative and should

be widely read. *Handbook on Social Hygiene*, by W. Bayard Long and Jacob A. Goldberg, Lea & Febiger, is a timely and authoritative symposium of 442 pages, giving technical guidance and basic philosophy in social hygiene.

TUBERCULOSIS

Tuberculosis is still a matter of constant interest in spite of the fact that we have learned so much about it and that our efforts at lessening the scourge have been so successful. *Tuberculosis Among Children and Young Adults*, by J. Arthur Myers, 2nd edition, Thomas, is the second edition of a book which first appeared in 1930 and gained considerable popularity. It has been brought up to date. *Pulmonary Tuberculosis in Practice*, by R. C. Wingfield, Wood, is a most interesting presentation of the subject with some ideas which are not accepted in America. It contains a wealth of information and is profitable to anyone interested in this disease. *The Collapse Therapy of Pulmonary Tuberculosis*, by John Alexander, Thomas, is a very unusual book, excellently illustrated, recommended to all interested in the subject of tuberculosis. This book on treatment is included, since among diseases the proper clinical care of pulmonary tuberculosis particularly is one of the most important measures in prevention.

VITAL STATISTICS

Graphs: How to Make and Use Them, by Herbert Arkin and Raymond R. Colton, Harper. This book should be on bookshelves next to *Statistical Methods* by the same author, Barnes and Noble, publishers. The entire book is written in the simple straightforward style that made *Statistical Methods* so valuable.

GENERAL

There are many books which might very well be classed under several

headings. The term general or miscellaneous is not at all satisfactory, but we use it for want of something better. Many of these books are educational along one line or the other. *Poisons, Potions and Profits: The Antidote to Radio Advertising*, by Peter Morell, Knight Publishers, is a thoroughly documented and devastating exposé of what radio is doing in advertising quack remedies. *Health, Hygiene and Hoocy*, by W. W. Bauer, Bobbs-Merrill, should be in every household. It is an excellent exposition of quackery, ending in an appeal to common sense. *Principles of Medical Statistics*, by A. Bradford Hill, The Lancet, Ltd., is a well balanced, well written book on elementary statistics prepared at the invitation of the Editor of the London *Lancet*. It is written for physicians primarily, but is also excellent for the health worker. *Report on the British Health Services*, by Health Group of PEP, PEP, 16 Queen Anne's Gate, is a notable book presenting a comprehensive picture of the health services of the British Empire with some criticisms and suggestions and is a most useful study. *Diet and High Blood Pressure*, by I. Harris, Longmans Green, is an excellent book for the "normal individual, and not for people suffering from high blood pressure." *Father's Doing Nicely, The Expectant Father's Handbook*, by David Victor, Bobbs Merrill, deserves a wide popularity. In spite of the many jokes which have been made, there is a great deal of reality in what have been called paternity pains. In San Francisco the new hospital has an expectant father's waiting room. Certainly the obstetrician has more trouble with the father than with either the mother or child. *The Sanitary Inspector's Handbook: A Manual for Sanitary*

Inspectors and Other Executive Public Health Officers, 3rd edition, by Henry H. Clay, Lewis, is admirable in every way and its usefulness is not localized by the fact that it was written around British acts, regulations, and by-laws. *Atlas of Skeletal Maturation (Hand)*, by T. Wingate Todd and Associates, Mosby, is an excellent study giving a basis upon which better standards may be created, but is too technical for general use. *Allergy: Its Practical Application*, by J. A. Rudolph, Dorrance, is a specialty which considers much more than making skin tests. There is a useful chapter on Immunology of Allergy. *How To Live*, by Irving Fisher and Haven Emerson, Funk and Wagnalls, 20th edition, is recommended without reserve for lay readers especially. *Osler's Principles and Practice of Medicine*, by Sir William Osler, 13th edition, Revision by Henry A. Christian, Appleton-Century, is a truly great work which has been acclaimed over the entire world. This revision is welcome in spite of some criticisms. *Successful living*, by W. Beran Wolfe, Farrar & Rinehart, is a good investment which has a high degree of useability for men and women in active life. *Legal Medicine and Toxicology*, by Thomas A. Gonzales, Morgan Vance and Milton Helpert, Appleton-Century. Out of their extensive experience in the Medical Examiner's Office in New York City the authors of this monumental work have produced an eminently practical text on the duties and activities of coroners and medical examiners, and the technicians employed by them. *The Public Assistance Worker*, edited by Russell H. Kurtz, Russell Sage Foundation, is as comprehensive a survey of the public assistance field as has yet been written.

A Brief History of Bacteriological Investigations of the United States Public Health Service—By A. M. Stimson. Supplement No. 141 to the Public Health Reports. Washington: U. S. Government Printing Office, 1938. 83 pp. Price, \$.15.

This is an interesting and useful compilation. It begins with the founding of the Public Health Service in 1798, tells of the establishment of the Hygienic Laboratory in 1887, gives short descriptions of the other research institutions operated by the Service, including the National Leprosarium at Carville, La., and the Kalihi Hospital in Honolulu, and includes a picture of the founding of the new National Institute of Health Administration Building in June, 1938.

Thirty-seven subjects, beginning with anaphylaxis, are covered alphabetically. The history of plague is particularly interesting. Many of us remember the situation in San Francisco when Kinyoun discovered plague there. It is an unsavory story and we wish it had been given at somewhat greater length. Finally the Public Health Service was asked to clean up Chinatown and, as Dr. Stimson says, "it actually performed this Herculean feat," but he does not say, as we think he should have done, that this was under the direction of Rupert Blue, afterwards Surgeon General. We can admit that Kinyoun had the roughest time and did not obtain the support he should have had from certain quarters but, next to him, Blue went through a most trying experience and he should be given credit for his splendid accomplishment of the task.

Under poliomyelitis, the experiment by Anderson and Frost in the transmission of the disease by the *Stomoxys calcitrans* is quoted with what seems to be indirect approval, though the author goes on to say that other officers of the Service, notably Leake, Bolton,

and Smith, soon convinced scientific people that *Stomoxys calcitrans* played no determining part in the transfer of the disease.

The most notable omission, and one which does not seem to be justified, is under the head of yellow fever. The author states the "bacteriological work relating to the disease was going sadly awry." He gives the findings of Geddings and Wasdin in confirming the claims of Sanarelli concerning the *B. icteroides* as the cause of the disease, for which they were decorated by the Italian government, though their error was promptly demonstrated. The author does not mention the fact that the U. S. Public Health and Marine Hospital Service, as it was then known, established a Yellow Fever Institute. In 1903, Working Party No. 1 of the Institute, consisting of Dr. Herman B. Parker, Assistant Surgeon, and Drs. George E. Beyer and O. L. Pothier, Acting Assistant Surgeons, made a report which was issued by the Government Printing Office, March, 1903, in which they described a "protozoan parasite," the "*Myxococcidium stegomyiae*," which they believed to be the germ of yellow fever. This should be included in any history of the work of the Public Health Service. Their claims were studied by James Carroll, a member of the Reed Commission, who made a devastating report which was published in the *J.A.M.A.*, Nov. 28, 1903, Vol. 41, page 1341, proving that the "protozoan parasite" was yeast probably derived from bananas.

Deserved tributes are paid to Dr. Kinyoun, the founder and first Director of the Hygienic Laboratory, who deserves all that can be said of him as an officer, a scientist, and a man, to Dr. George W. McCoy, who was Director of the Laboratory from 1915 to 1937, and to Dr. Joseph Goldberger, especially for his researches on pellagra, and to Dr. Henry R. Carter for his

brilliant epidemiological studies on yellow fever. All of these tributes are richly deserved.

One typographical error has been detected on page 38, which is unfortunate, since the history will perhaps be read by others than professional bacteriologists—"B. eoli communior." The booklet is a convenient reference for anyone interested in the history of the Service.

MAZŮCK P. RAVENEL

Avian Tuberculosis Infections—

By William H. Feldman, D.V.M., M.S.
Baltimore: Williams & Wilkins, 1938.
483 pp. Price, \$7.00.

The author's exhaustive researches are exemplified in this well written book, which reviews the literature, examines the extant data critically, and points the way for further investigation in the field of avian tuberculosis. The volume is a splendid contribution to the literature on tuberculosis.

It is pointed out that "the rôle of the avian tubercle bacillus in tuberculous infection is not well understood"; that "the ability of the bacillus of tuberculosis of chickens to infect a long list of heterologous hosts makes this member of the genus *Mycobacterium* of considerable importance to the student of infectious diseases"; that avian tuberculosis, which is the most widespread and economically one of the most important diseases affecting poultry, constitutes a problem of considerable magnitude to the \$200,000,000 poultry industry to the extent of losses aggregating to \$12,000,000 annually; and further, that "dissemination of the disease from infected poultry to swine and other mammals constitutes a problem the economic significance of which is perhaps equal to that caused by infection in the original host."

The first chapter gives a kaleidoscopic historical résumé of avian tuberculosis, its incidence and geographical distribution. The second chapter deals

with the biologic characteristics of the causative agent. A chapter is devoted to the isolation and culture of avian tubercle bacilli. There are sections on the diagnosis, the pathologic anatomy, and experimental tuberculosis in chickens. A detailed description is given of laboratory procedures for demonstrating tuberculosis infection in mammals and fowl. Four chapters deal with the pathogenicity of avian tubercle bacilli for fowl other than chickens, for certain mammals other than man, for cattle and swine, and for human beings. The author cites 13 specific cases of tuberculous infection in human beings in which the presence of avian tubercle bacilli appears to have been demonstrated, and then gives the details of 24 cases of alleged avian tuberculous infection in which the data were insufficient to support the diagnosis with the comment that "an analysis of the recorded data, obtained by reviewing the records as originally published, indicates that in the majority a diagnosis of avian tubercle bacillus infection was questionable or erroneous."

The author states further "when one considers the countless thousands of instances in which the type of the tubercle bacillus in human infections has been determined since the time of Koch, it may seem strange that the avian tubercle bacillus has been demonstrated so rarely. The explanation can only be that human beings have a formidable resistance to this particular form of the tubercle bacillus. The opportunities for infection are numerous, and if the avian tubercle bacillus were virulent in the accepted sense for human beings, it would seem reasonable to expect a far greater number of proved cases. Apparently, therefore, it is only the exceptional individual who becomes infected with the avian tubercle bacillus."

The book concludes with chapters on tuberculin testing and the public health aspects of the disease.

The enormous amount of research done by the author is significantly portrayed in the voluminous lists of references following the various chapters.

The photographs, tables, printing, and arrangement of material are in keeping entirely with the excellence of the subject matter. The book is recommended without reservation of any kind. BERNARD S. COLEMAN

Teaching With Motion Pictures: A Guide to Sources of Information and Materials—*By M. E. Townes. New York: Teachers College, Columbia University, 1938. 28 pp. Price, \$.25.*

Probably the most complete guide in print prepared for those "who use the motion picture as a teaching aid," its interest and helpfulness extends beyond the teaching field. It covers both educational and theatrical pictures. There is much for the parent and the student of motion pictures.

The information as to sources of existing pictures, and new pictures, is comprehensive. *Movie Makers* is omitted as a source of new pictures, and of free ones. "Making Motion Pictures in School" omits the National Board of Review as a source of information on school clubs and their picture production, confuses the mention of Amateur Cinema League, which is not a club, but a national source of information, through its magazine about local clubs and school made pictures.

EVART G. ROUTZAHN

An Introduction to Bacteriological Chemistry—*By C. G. Anderson. Baltimore: Wood, 1938. 278 pp. Price, \$4.00.*

This book does not attempt to be a complete treatise, but it covers the subject adequately for anyone who desires to obtain a general survey of the field. The material is treated under three major heads, covering the general

aspects of bacteriological chemistry, the metabolism of bacteria, and a summary of certain aspects of immunochemistry.

Although the author presupposes a knowledge of the fundamentals underlying the field, he gives in Part I an adequate summary of the physical chemistry of certain very important processes in bacteriology. This includes colloidal phenomena, the measurement and importance of hydrogen ion concentration, and oxidation-reduction potentials.

Part II, the metabolism of bacteria, contains chapters on the nutrition of autotrophic and heterotrophic bacteria, nitrogen and carbohydrate metabolism, the proteins, carbohydrates, and lipoids of microorganisms as well as a brief summary of industrial fermentations. Karström's work on adaptive and constitutive enzymes are adequately discussed.

Part III deals with the chemistry of antigens, haptens, antibodies, and complement as well as the mechanism of antigen-antibody reactions. A fairly complete summary of our knowledge of artificial antigens is given. The final chapter lists a few of the methods used in the isolation and identification of some of the metabolic products of microbial activity.

The author has made no attempt to deal with the chemistry of culture media, staining reactions, disinfection, or chemotherapy. The printing and make-up are excellent. There is a good index. OLIVER H. PETERSON

Lillian Wald, Neighbor and Crusader—*By R. L. Duffus. New York: Macmillan, 1938. 371 pp. Price, \$3.50.*

In presenting the great personality of Lillian Wald, the author also gives a somewhat intimate picture of the origin of many significant developments in American life which were guided in no small degree by the founder of Henry

Street Settlement. Miss Wald's genius in organizing and directing humanitarian enterprises, her rare humor and deep sympathy, her vision, and her active participation in liberal movements of her generation are vividly portrayed in this volume describing the career of one of the best known and beloved women of her time.

The conception and growth of public health nursing, including school nursing, the idea for the organization of the United States Children's Bureau developed at the breakfast table at Henry Street, important contacts in local, state, national, and international affairs, as well as glimpses of the daily life of Miss Wald, are described in a manner to interest a wide audience.

IRA V. HISCOCK

Maternity Care in a Rural Community—By *Maxwell E. Lapham, M.D.* New York: *Commonwealth Fund*, 1938. 65 pp. Price, \$.25.

This concise, readable, little volume should be of interest to public health workers and physicians practising obstetrics wherever conditions surrounding childbearing are similar to those prevailing in Pike County, Miss., which, the reviewer judges, is a typical "rural community." More than two-thirds of Pike County's citizens live in the country. Nearly half the mothers are delivered by ignorant midwives. Maternal and neonatal death rates are high.

The Pike County Health Department has sought to remedy the situation by furnishing the following services: prenatal and postnatal visits; clinics for medical examination of maternity cases not under a private physician's care; clinics for the treatment of syphilis; instruction and supervision of midwives.

This study, made through the coöperation of the Commonwealth Fund, the local practitioners and the local health

department, shows what was accomplished during the period 1931 to 1936. Using objective standards it gives a very detailed appraisal of the nursing services. It also evaluates with care the other health department activities and the current midwife and medical practice.

On the basis of the facts revealed, the author suggests specific ways in which every phase of maternity care as provided in Pike County could be improved. His recommendations are sound, practical, and of wide application.

HESTER B. CURTIS

Teachable Moments—*A New Approach to Health*—By *Jay B. Nash.* New York: *Barnes*, 1938. 245 pp. Price. \$1.50.

The title of this book refers to the moments when one is in a position to learn efficiently and rapidly. In the health field, the author states; there are at least four such moments: when a child exhibits curiosity or feels that differences make him conspicuous; in adults, when they are scared, or when, as parents, they want something better for their children.

Since such moments occur but rarely in a formally organized classroom, and since "there are not enough hygienic facts worthy of memorization to challenge an average intelligent child for over an hour a week for a semester," the author concludes that hundreds of thousands of dollars are being wasted each year "in earnest but misguided attempts to promote health through teaching hygiene." The child is much more apt to develop healthful habits if he gets his hygienic training in a home and a school which are in themselves wholesome, and which present surroundings conducive to proper health practices. It is the business of the adults to protect the children and to provide a wholesome environment for them; not to talk to them about health

and to make them thereby more self-conscious and afraid.

This challenge to health education is presented with a summary of the health facts which the adult needs to know in order to provide this wholesome environment. Attainment rests on a foundation of rest, sleep, and balanced diet, plus happiness, especially joy in one's work.

While many of the criticisms of modern health education are justified, one questions if a true picture has been presented of schools in general at the present time. The author holds promise for adult health education, although few constructive suggestions are given, as would seem desirable if it is to be the acme of health instruction.

Expressing challenging and critical statements about health education, the book should provoke discussion and stimulate thought about ways in which present methods of teaching health in schools can be improved so that no author can again call it "a remnant of the Middle Ages philosophy of scholasticism." MURIEL BLISS

Reference Handbook for Nurses
—By Helen F. Hansen. Philadelphia: Saunders, 1938. 347 pp. Price, \$1.50.

Miss Hansen's handbook, designed for anyone doing bedside nursing, should prove a welcome and valuable aid to the public health nurse. It contains in concise form information necessary to giving adequate, effective nursing care and to making intelligent observations.

A very practical bit of advice is given regarding the importance of keeping one's registration up to date and, before accepting a position in another state, ascertaining if one will be eligible there for registration.

The volume is divided into two parts. Part one discusses such topics as first aid, materia medica, frequently used

nursing procedures, and dietetic therapy. Principles of first aid in general and of emergency treatment of poisons in particular are discussed, as well as symptoms and treatment in conditions such as bites, fractures, hemorrhage, wounds.

Paragraph headings in heavy type facilitate finding information; cross references are made to places where a more complete consideration of a topic is given. The section devoted to materia medica includes a review of common weights and measures. Common drugs used are classified in the basis of site of action. The average dose, toxicology and treatment are briefly discussed. The fact that the use of protamine insulin is considered indicates that recent developments are included. A wide variety of frequently used nursing procedures, treatments, and diagnostic tests are presented. Stress is placed upon preparing the patient emotionally and utilizing opportunities to teach personal hygiene. The matter of sterilization of equipment is approached in a manner which makes it applicable to a home situation. Likewise, suggestions for improvised equipment may give new ideas for more effective care.

Part two, "Notes on Nursing," is particularly well written. It contains pertinent information related to medical and surgical conditions, communicable diseases, psychiatric nursing, obstetric and gynecological nursing, in which the preventive aspect is stressed. A brief discussion of child care emphasizes normal growth, development, and the ideal of positive health. Attention is called to the importance of regarding the child as an individual and guiding him in making adjustments to his environment.

Throughout, particular emphasis is placed upon preventive aspects and upon the opportunities of the nurse as a health teacher. The style is readable and clear. O. E. CARLSON

The Culture of Cities—By Lewis Mumford. New York: Harcourt, Brace, 1938. 586 pp. Price, \$5.00.

For over 15 years Lewis Mumford's writings have reflected a deep insight into the problems of decent human living as they are affected by the physical character of cities and urban housing. His latest book, widely hailed as a major contribution to the social thinking of our generation, will be of direct interest to many in the health profession for the light it throws on the relation between city building, housing, and the opportunities for an urban life which shall be not only healthful in the technical and statistical meaning of the term but vital and self-renewing in the broadest sense.

The first half of the book treats of the manner in which cities have grown since the Middle Ages, tracing (with the aid of consummately well chosen photographs) a steady decline in the fundamental human decencies from the walled medieval town to the vast, sprawling, crowded, unplanned aggregations of people and buildings, the "insensate industrial towns" of the 19th century. In a masterful first chapter which is one of the high points of the work, Mumford challenges the customary view of the medieval town as crowded and essentially unhealthful, holding it rather to have been relatively open, well-scaled to human needs and activities, and hygienically superior in many respects to the more complex cities which followed it down to the last half-century.

The decencies and amenities of living are shown to have been less and less considered as the city evolved from its primitive form through the Renaissance or Baroque city—with its emphasis on the broad avenue for military display, its grandiose architectural façades to glorify the agencies of political power—to the industrial megapolis which sacrificed all human

decencies to the planless crowding of workers near their shops and factories.

Though his damnation of the city as we have known it is hardly to be matched for vigor, Mumford is no medievalist, no advocate of return to the hand-loom and the subsistence-homestead as the road to a durable society. He does not argue the impermanence of the great city, but rather the possibility of humanizing it. The later sections of the book review the means at hand (some of them far more highly developed and better tested than is generally recognized) for this humanization: regional planning as a background for stable urban development; decentralization of metropolitan population and of the less specialized urban functions into satellite garden cities which can support the necessary specializations of the mother city; progressive community planning and modern housing as a means of rebuilding the mother city itself—all with the purpose of giving greater dignity and permanence to the physical city, new spirit and well-being to the human beings who comprise the city, and new vitality to the culture that is the city's excuse for being.

ALLAN A. TWICHELL

The Self You Have to Live With—By Winfred Rhoades. Philadelphia: Lippincott, 1938. 182 pp. Price, \$1.75.

This is essentially an inspirational book, a modern version of those treatises on life, of long and honorable literary history, that have drawn on the common sense and wisdom of the ages, back to the inspired scriptural writers and the ancient Greek philosophers from whom we have inherited treasures of knowledge held valid to this day. To the precept "Know Thyself" the present author adds the injunction "Live With Thyself," positing under this concept a rule of life that draws

liberally on the findings and teachings of modern psychology and psychiatry adapted to his personal philosophic predilections. Reflecting the lessons of his own life and a desire "to pass along to other suffering and struggling people some of the things I had learned in the hard and long school of personal sickness," his essay may be said to derive from a "variety of religious experience" that gave him motive power and insight making for healthy personal adjustment of a quality and degree he confidently considers attainable by others like-minded in their grasp and acceptance of certain underlying principles and attitudes.

It is a combination of spiritual and mental hygiene that we are offered in this treatise on "how to live," which is based also on the author's psychological work in the Boston Dispensary unit of the New England Medical Center, where he has conducted classes in "thought control" and helped and advised individuals with adjustment problems. While tenuous in its psychological material, it has great value, in the opinion of this reviewer, in the attention it gives to volitional factors and in its appreciation of the rôle of "will" in human behavior, which modern psychology tends to neglect in its preoccupation with thought and emotion. Hence the relevance of religion, as well as psychology, in human motivation and conduct, as emphasized by this writer and as other psychological writers are coming vaguely to recognize. But the "return to religion" must be rooted in sterner stuff and in solidier concepts of the nature and meaning of religion than some psychologists are offering us at this time, if the mechanists, determinists, and materialists of mental science are to be convincingly gainsaid. The present author, for example, defines religion as "intrinsically not a belief, not a doctrine . . . but conscious association with the divine Spirit and

Life." This is a pale formula to oppose to the negative convictions of the psychoanalyst who regards religion as an "illusion." PAUL O. KOMORA

Carbon Monoxide Asphyxia—By Cecil K. Drinker, M.D., D.Sc. *New York: Oxford University Press, 1938.* 276 pp. Price, \$4.50.

We have long known of Dr. Drinker's intimate knowledge of carbon monoxide poisoning and a profound textbook on the subject by him is a welcome and timely accession to the literature on this important subject. The work is dedicated to Oscar H. Fogg, first with the American Gas Association and later with the Consolidated Edison Company of New York, because of his untiring efforts for safety in the use of gas. It is written primarily for those who have practical concern with carbon monoxide asphyxia, and as a contribution to its intricate physiology and biochemistry. The detached point of view of both the medical investigator and the industrialist has been kept in mind. Chiefly facts, but some best theories, have been extensively culled from the literature and evaluated in relation to modern knowledge so that many authorities are cited and not a few quoted at length.

The reviewer is profoundly impressed with the care of preparation and the fine choice of language and description, which is always concise and practically never leaves any doubt in the reader's mind as to shades of meaning. The possibilities under different situations are almost invariably fully discussed, leaving few if any questions in the reader's mind. One senses throughout the strictly critical and impartial attitude of the true scientist who is thoroughly familiar with the subject he treats. The author has left the important chapter on analytical methods to Julius Sendroy, Jr., in which again one finds a masterful handling of the chief historical methods and the ac-

cepted present-day procedures, aided by three valuable tables, and guided by the opinions of the author as to the relative importance of various procedures.

Most valuable features of the text are the suggestions for further observations on various desired or controversial points.

This reviewer has found very little for critical comment. There is little repetition. Possibly a few paragraphs might have been included on the chemistry and metallurgy of carbon monoxide, the temperatures at which it may be oxidized to complete combustion under different conditions of physical surroundings, etc. The author has been very careful to distinguish between carbon monoxide and illuminating gas although there is some doubt on page 34, while Case No. 3 on page 41 is probably not a good selection since the patient could not be followed long enough. Also, in the table on pages 38-39, the previous condition of the hearts of the various cases had no doubt to be omitted as unknown, yet such would seem essential in establishing the circulatory effects on the patients after carbon monoxide asphyxia. On page 103 the author appears to be opposed to the requirement for ventilating all gas appliances with flue connections, but such a provision was enacted by the Ohio Public Health Council about 1923, covering all gas outlets in new construction, except those for lighting purposes only, and has appeared to be satisfactory, although the reviewer is conscious of the great lack of enforcement of the provision—due chiefly to lack of funds for supervisory services. In the table on page 142 it would strike the reviewer that all cases showing more than 115 per cent hemoglobin would imply a "conspicuous increase" whereas the author would include only three cases ranging from 134 to 154 per cent, but the point is a small one.

The exact complexion of what is

meant by "chronic" carbon monoxide poisoning is admirably handled. In regard to this form of poisoning, the author has apparently overlooked Charles Weisman (*Pub. Health Bull.* 81, 1917) on the "Effect of Gas-Heated Appliances upon the Air of Workshops," in which also appears a valuable Appendix B containing an abstract of an article by Morel and Mouriquand from a French source (1910) on a remarkable series of cases exposed for several years and followed up later.

We also note no comment on the use of nitrites in treatment, at the same time well recognizing, as Dr. Drinker says, "that practically every possible and impossible drug has been used in carbon monoxide poisoning."

When one faces the enormous literature on this, "the most widespread poison connected with human life and activity since the first discovery of fire," there can be no doubt that Dr. Drinker has selected and evaluated the essentials and drawn from his own experience the most masterful conclusions we have upon the subject at the present time.

EMERY R. HAYHURST

Proceedings, National Health Conference. 163 pp. Price, \$35.

The Nation's Health. 116 pp. Price, \$20.

Toward Better National Health. 30 pp. *By Interdepartmental Committee to Coördinate Health and Welfare Activities.* Washington: U. S. Government Printing Office, 1938.

Every serious student of the problem of providing adequate medical care will need to possess the first of these publications. It is a verbatim report of the National Health Conference, indexed by speakers. It includes the full report of the Technical Committee on Medical Care.

The second publication is intended to give the same information in a briefer and more readable form. Both

the proceedings and the report of the Technical Committee have been edited. Headlines and a running commentary are supplied and numerous extracts from speeches are included in eight-point type. The editors have been careful to underline harmony and to delete discord. The full story of the conference to be read comfortably in the proceedings is well worth the extra fifteen cents.

Toward Better National Health is frank propaganda* well illustrated with photographs from the Department of Labor, the Farm Security Administration, the Public Health Service, and the Works Progress Administration. It is designed to promote public support for legislation which will embody the proposals of the Technical Committee on Medical Care. Since dictatorial governments cannot function without propaganda, it is probable that democratic governments will be obliged to use increasingly all the instruments of publicity to state their case to the voters. Incidentally the exponents of popular health education may well study this pamphlet as an example of how it should be done.

* This word is used in the sense of "special pleading." It is not intended to imply the use of any artifice of deceit.

J. ROSSLYN EARP

Diseases of the Skin for Practitioners and Students — *By George Clinton Andrews (2nd ed.). Philadelphia: Saunders, 1938. 899 pp. Price, \$10.00.*

To the professional worker in public health there are likely to be two aspects of a treatise on dermatology in which he is specially interested, the Sections on syphilis and on the exanthemata.

The former may be said to receive adequate treatment, at least so far as the skin eruptions are concerned, in more than a hundred pages covering

this multiform disease. The diagnosis and treatment are described in terms of the findings of the Cooperative Clinical Group.

With respect to the exanthemata, the author apparently considers them not to be "diseases of the skin" and consequently dismisses scarlet fever and measles with only a word. It may properly be asked where an epidemiologist may expect to find help in the differential diagnosis of skin eruptions if not in such a text as this, especially when diphtheritic infection of the skin, tuberculosis of the skin, and many of the rare tropical eruptions are so fully described. The addition of such a section would enrich a subsequent edition for all public health workers.

As a whole, this volume may be regarded as excellent, partly because of the lucidity of the text and certainly because of the quality of the illustrations, of which there are 938. The author's treatment of the cutaneous manifestations of tularemia deserves special mention, and the section on leprosy is unusually good. A well prepared index rounds out a book, which can be recommended in its field.

REGINALD M. ATWATER

Medical Information for Social Workers—*By William M. Champion, M.D. Baltimore: Wood, 1938. 529 pp. Price, \$4.00.*

Dr. Champion and 8 coworkers from the Faculty of Western Reserve University School of Medicine present 30 chapters of medical information for the social worker "to enlighten beginners in social work and to enrich the medical knowledge at the command of the more mature social worker."

There are an introduction and three chapters dealing with the fundamentals of the social worker's need for medical information, historical aspects of medicine, and notes on the selection of a physician. Then follow 9 chapters

on diseases of the adult including, among others, diseases of the cardiovascular system, arthritis, rheumatic fever, respiratory diseases, endocrine disturbances, allergic diseases, syphilis, and tuberculosis. The section on pediatrics has 6 comprehensive chapters with special emphasis on the care of the new-born, "the first year," and on feeding and nutritional problems. The more common diseases of infancy and childhood are described.

The portion of the book devoted to surgery discusses indications for operation, blood transfusion, asepsis, trauma, amputations, and other conditions which have a definite medical-social significance, indicating the service the social worker can render to the surgeon and to the patient in explaining to the patient the need and indications for surgical treatment and in effecting adjustment of compensation claims, etc.

Nine chapters give medical information in the more specialized fields of cancer, gynecology, orthopedics, diseases of the ear, nose, and throat, and finally obstetrics.

Concluding this volume are an appendix on exercises in anatomy and physiology, and a bibliography of selected references to supplement the subjects discussed in the text. This collateral reference list has been chosen with care.

Throughout the book the reader is impressed with the simplicity of the language, the orderly presentation of the material, and the emphasis on the usefulness of the medical information to the social worker. It is only regrettable that some statements which are given as facts are not qualified. For example, in the chapter on tuberculosis, it is stated that this disease "still kills approximately 100,000 persons each year" in the United States. In 1937 there were 69,151 deaths according to the National Tuberculosis Association. Also, Dr. Koch discovered the tubercle

bacillus in 1882 and not in 1870, the date given.

In spite of some inaccuracies and scattered positive statements on moot questions the book should be helpful to social workers and others who are frequently in contact with the sick.

BERNARD S. COLEMAN

Biology and Pathology of the Tooth and Its Supporting Mechanism—By Bernhard Gottlieb and Balint Orban; translated and edited by Moses Diamond. New York: Macmillan, 1938. 195 pp., 166 ills. Price, \$5.00.

The views of Gottlieb, and later, of Gottlieb and Orban, on the physiology and pathology of the periodontal tissues have been known to the dental profession in America for a number of years, chiefly through articles in the journals. Now for the first time a comprehensive presentation of their findings is available in book form in English.

While not all American research workers are in agreement with all the beliefs held by these notable workers in the field, it remains true that they have satisfactorily elucidated many of the fundamental facts in this field on which tenable theories must be built. Particularly important is their presentation of the biology of the supporting mechanism of the teeth, to which the major part of the book is devoted. Throughout much emphasis is given, and rightly so, we believe, to the relations between the state of the occlusion (bite) and the health of the periodontal tissues.

In the section dealing with disease of the supporting tissues of the teeth, several statements are made that are of interest to the physician and public health worker. In discussing ulcerative gingivitis, the authors suggest that the fusospirochetal organisms may not be the cause of this condition since they are

found in many healthy mouths as well as in cases having this disease. The ready communicability of the disease in acute cases will lead the epidemiologist to question this statement, but the basic contention of the authors is undoubtedly sound as regards the true cause lying in a susceptibility of the tissues due to other factors. Again they state that pyorrhea is not so important a cause of toxemia from focal infection as periapical infection, since the pyorrhea pocket has free drainage. Careful evaluation of this statement is needed especially with regard to such factors as pocket depth and involvement of the bifurcations of the molar teeth.

In regard to pathology the authors reiterate their earlier statements that there are two types of periodontal disease, Schmutz (Filth) Pyorrhea and Diffuse Atrophy. Discussion of the latter condition is somewhat unsatisfactory due to lack of a definitive statement as to its nature and cause. Much light is nevertheless shed on the course of the pathologic processes under consideration.

Throughout the book the beautiful reproductions of histologic and histopathologic specimens assist the authors in presenting their views and add to the enjoyment of the reader. Here is presented for the first time, so we understand, a new process of photographic reproduction. The results are worthy of special comment.

The work of Diamond as translator has obviously contributed much to the readability of the book. Whether in agreement with all the views of the authors or not, the book is a "must" item for anyone who attempts to gain a real understanding of the periodontal tissues in health and disease.

JOHN OPPIE McCALL

Manual of Public Health: Hygiene
—By J. R. Currie, M.D. Baltimore: Wood, 1938. 324 pp. Price, \$5.00.

Dr. Currie, Professor of Public Health at the University of Glasgow and Examiner in Public Health for the License and Diploma of the Triple Board in Scotland, has prepared this manual of public health and hygiene primarily for the use of medical students. The volume is in the nature of a summary of subjects with which the health officer deals in his everyday duties, and recapitulates the subject matter in the course of public health to which medical students are exposed during their academic training.

The author has designed the book in a novel way undertaking to arrange the chapters so that priority is given to the "social aspects of Hygiene," that is, in the words of the author, "the attempt is made to follow the individual, in his relation to the social services, from his inheritance through his prenatal and infant existence, his young childhood and his school years to his active working life and finally, his old age." Thus there are short chapters on inheritance, maternity and child welfare, school hygiene, mental hygiene, industrial hygiene and social insurance. Only 4 pages are devoted to Public Health Administration (England and Wales and Scotland), and 10 pages to vital statistics. There is a section on Food. Then follow chapters on ventilation, heating, lighting, water supply, waste disposal, housing, and hospitals. Between the sections on the health services of communities and those on infection and infestation is a concise chapter on personal hygiene.

The concluding chapter on international health relations deals with sea and air-port sanitary regulations, protection against invasion by disease from foreign lands conveyed by the steamship and aeroplane, and finally with an account of air-raid precautions relating exclusively to civilian action in preparing against "war gas" attacks, with a description of methods for providing

collective and individual protection. The note on "Air Raid Precautions" has been added because "it now appears that in view of recent belligerents the unarmed civilian population of an enemy country is a fair mark for bomber aircraft."

The volume is precise. Fifteen tables and 34 photographs, diagrams, and drawings accompany the text. There is an index but no bibliography nor references, which, if carefully selected, would have enhanced greatly the value of the book. BERNARD S. COLEMAN

Air Conditioning for Comfort—By Samuel R. Lewis (3rd ed.). Chicago: Keeney Publishing Co. 285 pp. Price, \$2.50.

This is a good, lucid, elementary engineering text. It has little to do with public health. The second edition was reviewed in this *Journal* of March, 1936, p. 303. The present edition is reviewed favorably and more fully in the October, 1938, issue of *Heating, Piping and Air Conditioning*, the publication which carries the Journal Section of the American Society of Heating and Ventilating Engineers.

CHARLES LUNDY POOL

Nutrition and Diet Therapy—By Fairfax T. Proudfit (7th ed.). New York: Macmillan, 1938. 923 pp. Price, \$3.00.

This is the seventh edition of a book that has become very well known and widely used since its first appearance in 1918. The present edition has been revised and reorganized to comply with the new curriculum of the National League of Nursing Education.

In the section on normal nutrition every effort has been made to stimulate the student to do individual thinking. Laboratory lessons have been added to the dietetic section to coördinate with the different chapters of lecture material, and have been arranged in a

separate section to facilitate their use.

Laboratory work is appended to each chapter in the diet-therapy section as a practical application of the theory. In this manner emphasis is placed on the reasons for the modifications of the diet necessary to meet the specific pathological condition. The laboratory procedures may be carried out in the laboratory, classroom, or special diet kitchen as the situation permits.

The last section of the book contains a series of recipes for the dishes mentioned in the text, and also an appendix of over 60 pages giving very useful tables of food values, vitamin contents, ash constituents, etc., a personal health standard and scale, quiz questions on the text, and a list of reference readings.

An effort has been made—

To show the close relation of good nutrition to good health and to impress the student with the importance of maintaining a high level for her own health standards, stressing the part good food habits play in keeping her body fit. A course of reading has been suggested which should keep the student abreast of the nutrition work being carried on as part of a program for the peace and happiness of people throughout the world.

C. R. FELLERS

Sleep—By Ray Giles. Indianapolis and New York: Bobbs-Merrill, 1938. 290 pp. Price, \$1.75.

This popular treatise on sleep, "the secret of greater power and achievement," was written "to help you to enjoy your waking moments still more by improving your hours in bed." The book is based on psychological and physiological research of such authorities in the field as Dr. Donald A. Laird. Interspersed with this scientific background, are frequent quotations from the private sleep recipes of famous people, especially from authors, actors, and artists. While these quotations add popular appeal, the author properly questions how fully the suggestions should be advocated.

The book gives practical suggestions for the improvement of sleep, deals with the effects on sleep of various factors, such as evening exercise, night snacks, sleeping powders, beds and mattresses, light and noise, posture, diet, and worry. Throughout, emphasis is given to the relation of good physical condition and proper health habits to sleep. At the end of the book is given a list of 51 questions on physical and mental health habits and conditions. Perhaps insomniacs will discover the clue or even the underlying cause for their complaint in their answer to these questions.

One of the major criticisms of the book will probably be the fact that it presents many conflicting opinions, without giving, in some cases, correct conclusions, thus leaving the reader to draw his own. The author justifies this by the fact that there is disagreement on many phases of sleep, even among medical authorities. The book is interestingly written.

IRA V. HISCOCK

Bergey's Manual of Determinative Bacteriology—By David H. Bergey, Robert S. Breed, and E. G. D. Murray (5th ed., advance reprint). Baltimore, Md.: Williams & Wilkins, 1938. 77 pp. Price, \$1.00.

The preprint includes the Table of Contents for the book, 68 pages of general discussion, a Key to the orders of the class Schizomycetes and a Key to the families of the order Eubacteriales.

A Historical Survey of Classifications, omitted from the 4th edition, has been rewritten with emphasis on outlines proposed since 1923. It forms a valuable reference background.

The section on How Bacteria are Named and Identified is carried over from the previous edition.

The Rules of Nomenclature have been considerably revised in accordance with the revision of the International

Rules of Botanical Nomenclature (Amsterdam Congress, 1935) which are quoted in so far as they apply to bacteriological nomenclature.

Comment upon changes in the systematic position of various organisms is difficult until the complete text of the book becomes available. At a glance the reviewer sympathizes with the transference of *Klebsiella* to a position close to *Aerobacter* in the tribe *Escherichieae* but awaits with interest the reasons for placing *Serratia* in the family *Enterobacteriaceae* and the exclusion of *Alcaligenes* from this family. The family *Mycobacteriaceae* has probably been deprived justly of 6 genera which have been placed in other families. The change in the generic name of the glanders bacillus from *Pfeifferella* to *Actinobacillus* to *Malleomyces* is probably justified on the basis of priority; the last is a good descriptive name and we hope it has returned to stay but the reasons for its inclusion in the tribe *Pasteurelleae* are not fully apparent. Fortunately only the generic and specific names of organisms are commonly used; consequently they may be transferred from one tribe, family, or order, to others without disturbing the nomenclature. The names of genera and species become embedded in the literature. It is cause for gratification that only eight new generic names are introduced in the 5th edition of *Bergey's Manual*. Until more is known about the definition of a bacterial genus it is well to be conservative. As is recognized in the pages of general discussion of the reprint, the question of genera among the bacteria is at present largely a matter of convenience. In the past it was a matter of convenience (now outgrown) that all rod-shaped bacteria were called *Bacillus*. Largely because so many bacteriologists were working with the Gram-negative bacilli, it became convenient to divide these into a number of genera. It may be that

this division has gone far enough or even too far in some instances; e.g., it may be that *Escherichia*, *Aerobacter*, and *Klebsiella* will be found to form one natural genus and that *Eberthella* and *Salmonella* may form another. If generic distinctions of similar magnitude were applied to the many species of sporulating aerobes (*Bacillus*), sporulating anaerobes (*Clostridium*) and streptococci (*Streptococcus*) each of these genera might be subdivided into many genera. The responsibility for naming bacterial species is not quite so great, for, although knowledge of the organisms may be far from complete, the determination of stable differences under identical conditions provides a fair basis for specific differentiation.

The continued issuance of editions of *Bergey's Manual* is a sustained effort to evaluate and correlate the work of individual systematists and, under competent authorship, is of the utmost importance to bacteriology.

J. HOWARD BROWN

Safety Education Through Schools—*National Education Association, 1201 16th St., N.W., Washington, D. C., 1938. 60 pp. Price, \$.25.*

This is a "research bulletin" covering current school practices and teaching methods in elementary and high schools, and "necessary improvements in the teaching of safety."

Practically all forms of safety practice are represented in the list of 63 non-school organizations distributing free and inexpensive material—teaching guides, printed matter, plays, posters, films, slides, and film slides. Generous annotations seem to make clear what is available from each source. However, there is no evaluation of teaching values.

Under "Reviews of Safety Films and Slides," all necessary information is given as to 99 individual movies, 16 sound-slide films, and film strips. The

brief synopsis for each film and slide-film includes an attempt at evaluation, and an indication of the advertising content, if any.

Of course much of the material described is usable with adult audiences.

EVART G. ROUTZAHN

Penny Marsh: Public Health Nurse—*By Dorothy Deming, R.N. New York: Dodd, Mead, 1938. 266 pp. Price, \$2.00.*

This is one of a group of Course Books, presenting in entertaining story the "requirements, problems, pleasures, and future possibilities of selected fields of work" for young people. Penny Marsh does all of this and more. It is a well written, swiftly moving story of a young nurse who becomes a public health nurse.

The heroine becomes interested in doing visiting nursing in a small city, she takes a course in public health nursing, she becomes a county public health nurse on her own, with all the adventures a nurse might have. The climax is her experience in a flooded town on the Ohio—all of which is told with interest and authenticity. Nicely balancing the professional side is a love story, which reaches a satisfactory conclusion after some suspense.

Written for high school age and older girls, the book should be popular, and for a girl looking for advice on a career, this should help materially. In fact, many recruits might come to the ranks of public health nursing—there is such appeal in the story for the budding careerist. M. McC. Hiscock

Textbook of Anatomy and Physiology — *By Diana Clifford Kimber, Carolyn E. Gray, and Caroline E. Stackpole. (10th ed.) New York: Macmillan, 1938. 643 pp. Price, \$3.00.*

This excellent book was first copyrighted in 1893 and has now reached

its 10th edition. It has been improved and brought up to date. The added material brings it to such a level that it meets the requirements of the new curriculum but still in its simplicity and style it remains a tradition in the schools of nursing today. The correlation of the anatomy proper with the various organs and systems of the body makes the subject matter so easy to understand that the student nurses soon lose their fear complex as step by step they grasp the knowledge of the body structures and the life processes in which they take part. This old friend to the nurses in its new dress and form is better than ever before and will be welcomed by students and teachers and all interested in the nursing profession.

The printing and make-up are excellent. The illustrations are well chosen, abundant, and many of them are beautifully done in colors. A good example of these is found in those depicting the anatomy of the neck with the blood vessels in their proper colors.

Beginning with its first edition this book has always maintained a prominent position, and this 10th edition will be not only a joy to its old friends, but will appeal to new readers wherever teaching of nurses is carried out.

ELEANOR KEELY

Appertizing or The Art of Canning
—By A. W. Bitting, M.D. New York: The Glass Packer (11 West 42nd Street), 1937. 852 pp. Price, \$7.00.

Besides full familiarity with existing literature on the subject, the preparation of a complete and reliable text on canning requires specialized and practical knowledge which can be acquired only by long and close association with the canning industry. Therefore, on the rare occasions when a new book on canning is announced, the question logically arises as to whether the author is qualified to deal authoritatively with his subject.

However, in the case of this book, it is questionable whether any one individual now associated with the canning industry is better qualified than the author to cover the various phases of canning presented in the text. The name of Dr. Bitting—as well as that of his late wife, Katharine Golden Bitting—has been long and favorably known both to canners and to workers in the field of canning technology. Individually, and as a research team, their contributions are well known to workers in their field. This review would not be complete without a further word concerning the author.

The author's experience has included research on foods in Experimental Stations, in the Bureau of Chemistry, in the Research Laboratory of the National Canners Association, and as director of research for the Glass Container Association. During the World War he served in France in the planning branch of the Quartermasters Corps. In the course of his work as consultant, he was selected as adviser on food exhibits to A Century of Progress Exposition. It is from the wealth of experience gained from such close and varied relations with the canning industry that the author's present complete and constructive contributions to the rather limited literature on canning has been made.

The book, "Appertizing"—whose title is coined from the name of the discoverer of the principle of canning—constitutes a veritable "gold mine" of information on commercially canned foods, not only for practical canners, but for students of food technology, health officers, and food regulatory officials, as well. The amount of space allotted to this review will permit only a limited description of the organization and contents of the book.

The text is organized into a number of major sections, the first of which—dealing with historical aspects—is from

the pen of Mrs. Bitting. In this section, comprising some 117 pages, are collected in their original forms historic patents and papers relating to canning dating forward from the time of Appert. This is a unique feature of the book in that no previous publication has brought together in one place, for example, the original papers of Prescott, Underwood, MacPhail, Russell, and Barlow, which in their entirety laid the foundations for the modern science of canned food microbiology.

The remainder of the book is devoted to the canning of foods, the major sections dealing with the packing of fruits, vegetables, specialty products (spaghetti, etc.), milk, meats and allied products, fish and sea foods. The various products are discussed alphabetically within the particular sections into which they fall. Each discussion on any specific canning procedure contains valuable detailed information, consequently it is difficult to indicate here in a general way the nature of the details presented.

However, using corn as a specific example, some of the major items discussed might be described. After covering the botanical position and origin of corn, the varieties commonly used for canning, the early history of corn canning in America and the production figures for corn since 1912, the author first passes to chemical and physical changes in corn during development and after harvesting; then to the U. S. Standards (1935) for sweet corn for canning; and finally to the details of the packing procedure. Other useful points of information are also included such as the Bureau of Agricultural Economics Standards for Cream Style and Whole Grain Corn; Service and Regulatory Announcements affecting canned corn (under the Act of 1906); and common difficulties encountered in canning. This résumé will indicate the thoroughness with which the author

treats the technological and practical aspects of his subject.

The major suggestion which might be made for improvement of the text relates to the organization of the index rather than to the contents of the book. The index is not as complete as might be desired in a volume of this size. While alphabetical listing is employed for products included in the various sections on canning procedures, the reader's convenience would have been better served by a more complete cross-indexing of the text, particularly when a specific point of information is desired.

As offered to the reader, however, "Appertizing" should prove a valuable addition to the libraries of persons who deal either intimately or only occasionally with commercially canned foods. It is recommended without hesitation to all workers in the field of public health who have need of a reliable reference text of this character.

F. F. FITZGERALD

Facts About Food—By S. Henning Belfrage, M.D. New York: Oxford University Press, 1938. 177 pp. Price, \$1.50.

This is a popular little book on diet by an English physician, who writes interestingly and authoritatively about the various functions of food in the body and the best uses of various food-stuffs for well balanced and economical diets. The book is well printed, but has no index. It should be of value to the general reader.

JAMES A. TOBEY

The Health Program in Small Associations—By Edith M. Gates. New York: Womans Press, 1936. 57 pp. Price, \$.65.

This is a discussion as to the set-up of health programs in small Y.W.C.A.'s. It discusses the type of organization that would be advantageous. It has a

section on health education and the type of lectures and projects that are advisable; one on physical education sketching the activities of gymnasium classes and individual work in such activities as swimming, tennis, bowling, tap dancing, and the like; and one on recreation, either tied up with the physical education program, or aside from it. At the end is an 8 page bibliography. CHARLES H. KEENE

Marihuana: America's New Drug Problem—By Robert P. Walton. Philadelphia: Lippincott, 1938. 223 pp. Price, \$3.00.

This is an authoritative discussion of the scientific uncertainty and scholastic ignorance which surround the resinous exudate of the hemp plant. The author has chosen to call this marihuana, though he does not tell us why. Among several pages of alternative titles, this one is described as "the name given the weed in Mexico and the Latin American countries" (but would the Spanish peoples use that letter h?) and it is derived from "maraguango" meaning any substance producing an intoxication.

The one thing certain about the history of our subject is that hemp was a reasonably common plant in various pre-Christian civilizations. But as soon as one authority has theories regarding its early use another authority seems to disapprove. Creighton thought that the grass ("hashish") on which Nebuchadnezzar fed was hemp, and that the first chapter of Ezekiel was written by a marijuana addict. Most of us would have accepted his suggestion were it not that Dr. W. C. Graham who teaches Old Testament at the University of Chicago finds these theories unconvincing. De Sacy's theory that Assassins were originally hashish eaters has many apologists among the pamphleteers and has been naïvely accepted by the *Encyclopaedia Britan-*

nica; but there are other philologists who doubt.

Some say that marijuana causes addiction. Others say not. Dr. Walton is convinced that "there is a certain degree of addiction when this drug is smoked for an extended period of time." There is no doubt that men commit crimes while under the influence but it is seldom easy to decide whether the crime was planned before taking the drug or was committed without premeditation. The pathology is unknown and even the pharmacology has its doubtful points. For instance 22 c.c. of fluid extract did not kill a 40 lb. dog but 10 c.c. more rapidly injected did do so. No one knows whether the dog died from cannabinal, or alcohol, or precipitated resin. Modestly included in the pharmacological research is an item which on consulting reference number 417 in the bibliography turns out to be work done by the author himself and published in 1938.

Whether the effects of taking hashish are aphrodisiac, whether they are even pleasant, is a matter on which experiences do not accord. Dr. Walton points out that Dumas's famous description of a voluptuous fantasy in *The Count of Monte Cristo* "has never been incriminated in the development of any hashish addiction." This fact he adduces in support of his thesis that literature has little or no influence on the propagation of this sort of vice. Perhaps there are other readers, like myself, who do not feel themselves seduced by those marble goddesses with their breasts of ice and their burning mouths.

What can be done? Dr. Walton tells how the police in New Orleans have, by arrests and seizures, forced up the price of marijuana cigarettes to 30 or 40 cents each. He believes they can be made even more expensive. But he is not over-optimistic: "... the vice still

flourishes in every country in which it has once been established. This is despite the fact that, in some of these countries, attempts have been made for almost 1,000 years to stamp out the practice." J. ROSSLYN EARP

Health Insurance with Medical Care: The British Experience—*By Douglass W. Orr, M.D., and Jean Walker Orr. New York: Macmillan, 1938. 271 pp. Price, \$2.50.*

Out of the plentiful accounts on the British Health Insurance system, which include elaborate reports of two Royal Commissions and numerous technical documents, comes the Orr book, the first thoroughly readable and enjoyable account of the subject.

At the outset they state that "The English scheme is neither . . . centralized nor . . . simple." With the National Health Insurance, the main theme, they clearly weave into the pattern the important services such as public medical services, public assistance medical care, and voluntary contributory insurance that comprise the English health insurance system.

According to the Orrs, public health work in the medical inspection of school children and maternity and child welfare work, marked one of the major steps in the drive for health legislation in England. It has been pointed out that National Health Insurance is restricted in scope through its failure to provide specialist and hospital services, and care for dependents of insured persons. Nevertheless, the scope of public health work, which also includes many welfare activities, is such that "theoretically no one in England need go without medical care." These services are further implemented by numerous medical agencies, so that practically 40 per cent of the entire population and 80 per cent of gainfully employed persons are covered.

The network of medical services available to the English people is described succinctly and well. The Orrs' belief in the effectiveness of these services is perhaps too rosy when one considers health conditions in the slums of London, Manchester, and Birmingham. Their sample of physicians' incomes is equally idealized.

In their desire to learn what the English people think of health insurance, the Orrs went directly to the "producers"—the practising physicians, officers of the British Medical Association, and government officials—and the "consumers" of medical services. There is a unanimity of approval in both groups, even that the services should be extended. In light of the repeated assertions on the part of the American Medical Association to the contrary, this testimony is significant.

JOSEPH HIRSH

The Professional Secret in Social Work—*By Rev. Walter McGuinn, S.J., Ph.D. Boston: Boston College School of Social Work, 1938. 34 pp.*

The author presents a framework of moral principles calculated to guide the social worker in the solution of problems rooted in the social work secret. Consideration is given to natural, promised, and entrusted secrets, including the professional character of relationships with clients. Among the several conclusions, it is indicated that the obligation ceases when the preservation would cause serious harm to the community, and the Social Work Secret must be revealed when the preservation would jeopardize public peace, public health, public morals, or public welfare. But in solving a concrete case of conflicting rights and duties, the benefit of the doubt to the client must call for a preservation of the secret unless there is a clear necessity of making the revelation.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Dental Abnormalities and Syphilis—Are "Hutchinson's teeth" pathognomonic of congenital syphilis? Are defects of teeth other than the upper incisors equally suggestive? Can defects of enamel from other causes than syphilis be clearly differentiated? Answers to these questions are sought for, and some good photographs are included which will be of interest.

ANDERSON, B. G. Dental Defects and Congenital Syphilis. *Am. J. Dis. Child.* 57, 1:53 (Jan.), 1939.

American Failures and Successes—As told to an international group in Scotland, our recently adopted National Health Program sounds most promising. At any rate it will do American sanitarians good to look at the picture of public health administration a-la-U. S. A., as displayed for the edification of others.

BAUMGARTNER, L. Recent Developments in Public Health in U. S. A. *Medical Woman's J.* 46, 1:21 (Jan.), 1939.

Childhood Conditions Causing Deafness—Experience is reported which leads to the conclusion that if school children in the primary grades were examined with a nasopharyngoscope at least once each year and those with lymphoid tissue about the eustacean tubes were treated with radiation, half the deafness in the next generation could be prevented.

CROWE, S. J., and BAYLOR, J. W. The Prevention of Deafness. *J.A.M.A.* 112, 7:586 (Feb. 18), 1939.

Do Nurses Influence Health Behavior?—We say, glibly enough, that the public health nurse is the teacher of hygiene in the home, the health educator *par excellence*, the mentor of the

family in matters of household hygiene. But is she? Is she equipped from the standpoints of adult education, applied psychology, or physiology to meet all our assumptions? To find out, competent stenographers were sent into the homes with the nurse to record what transpired. How, and how not, to teach are pointedly illustrated by some swell snatches of conversation between nurse and client. They must be read in their entirety.

DERRYBERRY, M. How May the Nurse Become a Better Teacher? *Health Officer.* 3, 9:253 (Jan.), 1939.

A Con Is Heard—Our British cousins, who delight in understatement, would characterize this as a rather forceful criticism of the recently proposed National Health Program. The author asserts that the public health services are not only not grossly inadequate, but that, on the contrary, we are at the very zenith of progress toward national health; that the sick poor receive a high quality of medical care; and that health departments should have nothing to do with services for the indigent sick. This paper is upon one of those topics about which each will want to make his own annotation.

EMERSON, HAVEN. Signs of the Times in Public Health. *J.A.M.A.* 112, 8:737 (Feb. 25), 1939.

Body Build and Birth Canals—Health workers in the field of maternal and infant hygiene will find much of value in these pelvimetric studies which demonstrate that a properly "normal" female pelvis occurs in less than a third of the women studied. The rest bore an embarrassing resemblance to the primitive pelvises supposed to be found only in Hottentots and Bushwomen.

Others than hygienists will be interested in the study because it shows how uncritically we take for granted any misinformation that has become bearded with moss.

GRUELICH, W. W. A Study of Pelvic Type. *J.A.M.A.*, 112, 6:485 (Feb. 11), 1939.

Is a Man as Old as His Arteries?—This paper is notable as an attempt to put to scientific test a hygienic "old saw." Let us hope that this effort will stimulate a whole epidemic of similar studies. "A man is as old as his arteries" is the overworked axiom subject to scrutiny. The tensile strength of the aortas of young and old rats and of rats subjected to alcohol and other health hazards was determined. It would not be fair to retail all the findings here, for the paper should be read, if only for its pioneering values.

HUME, J. F. The Tensility of the Rat's Aorta as Influenced by Age, Environment, Temperature, and Certain Toxic Substances. *Am. J. Hyg.*, 29, 1:11 (Jan.), 1939.

Mental Health in Child Hygiene—Reported upon is a 2 year study in preparing nurses to help mothers understand child development, and to help them anticipate and prevent undesired mental habits in their children (not to treat existing mental problems). An adviser in parent-child relationships spends a day or two in the field with each child hygiene nurse, after the nurse has become familiar with the principles of mental hygiene.

LEVY, J. An Experiment in Training Nurses to Help Mothers in Preventive Mental Hygiene. *Ment. Hyg.*, 23, 1:99 (Jan.), 1939.

Pneumonia in the North—In this series of Canadian papers upon epidemiology and treatment of pneumonia there seems to be no marked divergence from the findings reported on this side of the border, but public health administrators will find some useful comparisons here with local experience.

McKAY, A. L., *et al.* Epidemiology and Etiology of Pneumonia (and four other papers). *Canad. Pub. Health J.*, 30, 2:69 (Feb.), 1939.

A Hundred Million Dollar Industry—In this excellent statement of the problem of caring for the mentally sick, which is intended for the educated laity, health workers will find much of interest. A plea is made for more mental hygiene in our new National Health Program.

OVERHOLSER, W. Mental Hygiene—a Challenge. *Sci. Month.*, 48, 3:203 (Mar.), 1939.

Metabolic Disturbances and the Wassermann—False-doubtful and false-positive results are obtained from the sera of non-syphilitic but tuberculous blood donors, so it is evident that tuberculosis toxemia *may* add a confusing factor to syphilis serology. It is evident from this study, however, that it need never create a major difficulty in serodiagnosis.

PARRAN, T., and EVERSON, K. The Effect of Tuberculosis on the Serological Reactions for Syphilis. *Am. Rev. Tuberc.* 39, 11:1 (Jan.), 1939.

Skin Cancers Versus Internal—It appears that sailors in the U. S. Navy have a higher percentage of exposed cancers (due to the skin irritants, sun, salt water, and wind) and fewer internal cancers than the comparable civil population. If irritation chooses the organ to be attacked, providing the body is disposed, it might be possible to change the distribution of cancer in the direction of accessibility of treatment. Perhaps the well known hazard of sun and salt water is really a boon to the sailor.

PELLER, S., and STEPHENSON, C. S. Cancer in the United States Navy. *Am. J. Hyg.* 29, 1:34 (Jan.), 1939.

Children's Food—Scandinavians took a great step in school child nutrition when, instead of a hot noonday

luncheon, they were persuaded to substitute the now world-famous "Oslo Breakfast," served first thing in the morning. It consists of whole wheat or rye bread, cheese, milk, reinforced margarine, and half an apple, or substitute. In the article is a great deal about the vitamins, and calcium and iron. Concluding is a covenant of faith.

ROSE, M. S. Nutrition and the Health of the School Child. *Am. J. Dietetic Assoc.*, 15, 2:63 (Feb.), 1939.

Protecting Students in Institutions—Instead of being almost universal, the incidence of tuberculous infection in our present younger generation is less than half. The most exposed groups are medical students and nurses in training. Much of these infections could be prevented and the institutions should be obligated to protect these young people.

SOPER, W. B., and AMBERSON, J. B. Pulmonary Tuberculosis in Young Adults. *Am. Rev. Tuberc.*, 39, 1:9 (Jan.), 1939.

Health for 78,000 Farm Families—More than 600,000 low-income farm families receive financial aid from the Farm Security Administration. On the assumption that loans will be repaid more readily if borrowers are well, the federal agency has arranged through local medical societies for prepaid medical services. The scheme has been extended over 13 states and agreements have been reached with state medical associations in 7 others.

WILLIAMS, R. C. Medical Care Plans for Low-Income Farm Families. Health Officer. 3, 9:245 (Jan.), 1939.

Births and the Wee Sma' Hours—Stillbirths and neonatal mortality rates are higher among children born between noon and midnight than during the other half of the day: between 3 and 6 in the afternoon is the worst time. Operative deliveries are highest then, too.

VERUSHALMY, J. Hour of Birth and Stillbirth and Neonatal Mortality Rates. *Child Development*. 9, 4:373 (Dec.), 1938.

ASSOCIATION NEWS

SIXTY-EIGHTH ANNUAL MEETING

Pittsburgh, Pa.

October 17-20, 1939

HEADQUARTERS — HOTEL WILLIAM PENN

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Ernest L. Berry, M.D., Box 343, Buhl, Idaho, Administrator, South Central Unit
Charles B. Billington, M.D., C.P.H., P. O. Box 445, Richmond, Ky., Madison County Health Officer
Hugh G. Clark, M.D., County Health Dept., La Fayette, Ala., Chambers County Health Officer
Valentine S. Duff, 8 Smith Rd., Hingham, Mass., Executive Health Officer
Littleton H. Eubanks, M.D., Lexington, Miss., Holmes County Health Officer
Thomas K. Fairey, M.D., 17 Edisto St., Johnston, S. C., County Health Officer
Robert S. Genduso, 654 Broadway, West New York, N. J., Health Officer
William B. Harrell, Jr., M.D., Box 332, Jonesboro, Ark., Craighead County Health Officer
Paul J. Jakmauh, M.D., 449 Eliot St., Milton, Mass., State Commissioner of Public Health
Festus E. Kitchens, M.D., 2506 Ponce de Leon, Coral Gables, Fla., Health Officer
C. A. Lusk, M.D., Walton Bank Bldg., Butler, Mo., Deputy State Health Commissioner for Bates County
Paul G. Martel, City Hall, Chicopee, Mass., Agent, Health Dept.
John G. McNiel, M.D., Christiansburg, Va., Montgomery County Health Officer
Lewis A. Nimmons, M.D., Bishopville, S. C., County Health Officer
Herman W. Schweizer, M.D., Fort Hall Agency, Fort Hall, Idaho, Agency Physician, U. S. Indian Service
Richard N. Sherwin, M.D., Court House,

Hillsboro, Ore., Washington County Health Officer
Leigh A. Simpson, M.D., 11 S. 3rd, Fulton, N. Y., Health Officer
Clarence G. Thompson, M.D., Disco Bldg., Norwich, Conn., Health Officer
Francis B. Wishart, M.D., D.P.H., 21 George St., Campbellton, N. B., Canada, District Medical Health Officer
George C. Wood, M.D., Ft. Belknap Hospital, Harlem, Mont., Senior Physician, U. S. Indian Service
Jack Woodward, M.D., D.D.S., Hoopa, Calif., Senior Physician, U. S. Indian Service

Laboratory Section

EMPLOYMENT SERVICE

The Employment Service will register persons qualified in the public health field without charge.

Replies to these advertisements, identifying clearly the key number on the envelope, should be addressed to the American Public Health Association, 50 West 50th Street, New York, N. Y.

POSITIONS AVAILABLE

The U. S. Civil Service Commission announces examinations for:

Associate Public Health Nursing Consultant, \$3,200 a year

Assistant Public Health Nursing Consultant, \$2,600 a year, with U. S. Public Health Service, Treasury Dept.
and

Associate Medical Officer, \$3,200 a year (General Practice) with Veterans' Administration.

Applications must be on file not later than April 10, 1939 or April 13 for western states. Forms may be procured from any first-class post office or from the Civil Service Commission, Washington, D. C.

There is a vacancy in the position of assistant professor in the Department of Bacteriology, Hygiene and Preventive Medicine at Baylor University College of Medicine, Dallas, Texas. A man primarily trained as a bacteriologist, also in general public health who likes to teach, is sought for this position. Applicants may communicate with Hardy A. Kemp, M.D., Professor, relating experience and salary desired.

POSITIONS WANTED

HEALTH OFFICERS

Experienced public health executive; 10 years as full-time county health officer; 4 years as state commissioner of health, wishes administrative position of responsibility. A403

Unusually well qualified and experienced administrator, M.D., Johns Hopkins; M.P.H., Harvard; with broad experience in administering programs of medical care, is available. A404

Physician, M.D., Class A medical school; M.S.P.H., University of Michigan, 1937; now serving as district state health officer, seeks full-time city or city-county administrative position. A367

Well qualified physician, with C.P.H. from Johns Hopkins; experienced as school physician and in college teaching, will consider city or county administrative position or teaching and student health service. A383

Physician, M.D., Vanderbilt University; Dr.P.H., Johns Hopkins; experienced as epi-

demologist, health officer and professor of preventive medicine, seeks position as administrator or epidemiologist. A397

Physician, aged 30; M.D., University of Illinois; C.P.H., University of California; experienced as instructor in medicine and director of state Division of Epidemiology, desires position in communicable disease control or administration. A399

Physician, M.D., C.P.H., two years' experience as district health officer; prefers to do venereal disease control work or epidemiology. A345

Well qualified physician, completing course in public health at the University of Michigan, with special interests in tuberculosis and venereal disease control, seeks a responsible appointment. Excellent references. A406

Physician, M.D., University of Minnesota, 1927; M.S., Columbia University, 1937; special training in tuberculosis and venereal disease, and administrative experience in CCC camp, wishes position as health officer. A407

HEALTH EDUCATION

Health educator with excellent background of teaching experience in schools; M.S.P.H. from the University of Michigan in June; wishes a position where skill with educational sound film projection and other recognized technics will be appreciated. H405

Experienced director of health education, R.N. and college graduate, with excellent references, will consider health education or promotional position in the East. H408

LABORATORY

Physician, M.D., Northwestern; Dr.P.H., Johns Hopkins; broad experience in laboratory, teaching and epidemiological fields, will consider temporary position for summer, beginning in April, preferably in parasitology. M293

Physician, C.P.H., Harvard-Technology; experienced as bacteriologist and pathologist and director of state laboratories, desires position. L208.

Experienced bacteriologist, Ph.D., 1934, with teaching in research background, particularly in relation to sanitation, seeks position as director of laboratory or teacher. L370

NEWS FROM THE FIELD

NATIONAL CONFERENCE FOR COÖPERATION IN SCHOOL HEALTH EDUCATION

RECOGNITION of the opportunities for developing more comprehensive and better coördinated programs of school health education throughout the United States culminated in a 2 day conference of some 70 delegates of 40 national organizations at the Rockefeller Center, New York, in November, 1938. Preliminary plans for the conference were developed by representatives of the National Education Association, the U. S. Public Health Service, the American Social Hygiene Association, and the National Health Council. Reports from delegates gave a colorful picture of the variety of ways that different organizations operate, of the wealth of diversified services, of the many groups served, and of the difficulties which hinder full attainment of objectives.

Members of the conference stressed the importance of health education in the entire community and the desirability of interrelating school health education and public health education as parts of that whole. There are many national health and educational agencies already well organized for service in this field. From this preliminary conference there resulted a plan for the organization of a National Conference for Coöperation in School Health Education "To meet more effectively the recognized needs of the schools . . . for making the resources of those agencies more readily available through coördination of efforts."

An executive committee is in the process of organization, and operating codes have been tentatively drawn up for the guidance of the executive committee and of the National Conference composed of representatives selected by

the national agencies represented at the first Conference and others to be added. These plans will be submitted in the near future for the consideration of the participating agencies. The chairman of the Conference during these stages of organization is Professor Ira V. Hiscock of Yale University, President of the National Health Council. The secretary is N. P. Neilson, Ph.D., Field Secretary of the American Association for Health, Physical Education and Recreation of the National Education Association.

SOUTHERN CALIFORNIA PUBLIC HEALTH ASSOCIATION ELECTS OFFICERS

AT its recent Annual Meeting the Southern California Public Health Association elected the following officers:

President—Wilton L. Halverson, M.D., Pasadena

President-elect—C. Morley Sellery, M.D., Los Angeles

First Vice-President—Hyman I. Vener, M.D., Los Angeles

Second Vice-President—Charles R. Wylie, M.D., Ventura

Secretary-Treasurer—R. L. Kaufman, M.D., Riverside

BIRTH CONTROL AGENCIES MERGE

THE American Birth Control League and the Birth Control Clinical Research Bureau have merged to form the Birth Control Federation of America, following ratification by the League of the action of a joint committee presented at its 18th annual meeting in New York on January 18.

Dr. Richard N. Pierson, of New York, Chairman of the Joint Committee, was elected temporary President of the new Federation, and Mrs. Margaret Sanger was elected Honorary Chairman of the Board.

HYGIENE OF HOUSING COMMITTEE

THE regular spring meeting of the Association Committee on the Hygiene of Housing, under the Chairmanship of Professor C.-E. A. Winslow of Yale University, was held as a round table under the auspices of the Milbank Memorial Fund at the New York Academy of Medicine, March 23 and 24. On March 25 the Committee continued its discussion in New Haven at Yale University and at the Pierce Laboratory of Hygiene.

In addition to the 18 members of the Committee, and the staff attached to the Committee, other participants were W. H. Purnell, in charge of TVA research in house heating; Dr. Svend Riemer, a Swedish-German sociologist who conducted studies in Stockholm on family living habits as affected by the plan of the dwelling; L. M. Graves, M.D., Health Officer of Memphis; Henry F. Vaughan, Dr.P.H., Health Officer of Detroit; Coleman Woodbury, Director of the National Association of Housing Officials; J. I. Linde, M.D., Health Officer of New Haven; Huntington Williams, M.D., Commissioner of Health of Baltimore; Dr. Abraham Goldfeld, Director of the Lavanburg Foundation, and Mr. B. M. Pettit, Director of the New Haven Housing Authority.

THE WANGER HEALTH BILL

THE Wanger health bill, which has been referred to the Senate Committee on Education and Labor, is having the consideration of Senator Elbert D. Thomas of Utah, who has sent copies of the bill to all administrative agencies, asking for comments.

It is understood that hearings will be scheduled when these federal agencies reply, and it is reported that Senator Thomas will conduct the hearings himself before the whole Committee, and is not planning to appoint a sub-committee.

The Chairman is reported to be a scholar of some distinction, holding doctorates at four universities, and the Senate Committee on Education and Labor is an unusually able and socially minded group, who will give the National Health Program bill a sympathetic hearing. Other members of the Committee are: Senators David I. Walsh, James V. Murray, Vic Donahey, Rush D. Holt, Claude Pepper, Allen J. Ellender, Josh Lee, Lister Hill, William E. Borah, Robert M. LaFollette, Jr., James J. Davis, and Robert A. Taft.

NORTHERN CALIFORNIA PUBLIC HEALTH ASSOCIATION ELECTS OFFICERS

THE following officers for the year 1939 were elected by the Northern California Public Health Association at its annual meeting held on February 25th:

President—Louis Olsen, Palo Alto

President-elect—I. O. Church, M.D. Oakland

Vice-President—A. Frank Brewer, M.D., Fairfield

Secretary—Miss Margaret Blee, Berkeley

Treasurer—Miss Helen Hartley, Stockton

Representative on A.P.H.A. Governing Council—Guy S. Millberry, D.D.S., San Francisco

Alternate—Fred T. Foard, M.D., San Francisco

WESTERN UTAH TO HAVE PUBLIC HEALTH NURSING SERVICE

ARRANGEMENTS have been completed for a public health nursing service to be established in the Goshute Area in western Utah. The service will be financed by three agencies: Tooele County, Utah; the Utah State Board of Health; and the U. S. Indian Service—each paying one-third of the total cost.

Owing to the geographic isolation of this area, medical services have been very meager in the past. The nearest physician is about 100 miles from the center of the area, and the nearest hospital is at Ely, Nevada.

DECLARATION OF THE BALKAN MEDICAL UNION

THE Balkan Medical Union, in session at Istanbul (December, 1938),

having taken into consideration the terrible sufferings which a war will bring upon the civil population of open towns, together with the total lack of any adequate means of protection,

and having discovered that even in its restricted form the project of "sanitary towns" has not yet been adopted, and that all efforts made to protect civilians against chemical warfare have till now remained as proposals only, and that even the protocol prohibiting the use of asphyxiating gas has not yet been ratified by all nations,

has therefore decided to address itself to doctors of every nation with an appeal to take active measures and to fulfil this professional and humanitarian duty of awakening and stirring public opinion.

The Balkan Medical Union believes that only enlightened international opinion can make plain the imminence of the danger and the proved uselessness, even for the victor, of these terrible atrocities, and can thus lead to effective action.

The immutable truth that hate breeds only hate, and atrocity breeds vengeance must be impressed on everyone.

UNION MÉDICALE BALKANIQUE

22, Peyikhane caddesi, Istanbul

THE PROFESSIONAL CLUB—NEW YORK WORLD'S FAIR

THE Professional Club, an incorporated organization, will mark the first time in any international exposition that physicians and public health workers will occupy club quarters especially reserved for their use.

The Professional Club is to occupy an area of 5,000 square feet on the main floor of the exhibit building, with

a main entrance from the garden between the science and medical wings of the building, and another from the Hall of Man. Its lounge, designed by Franklyn Fischer, is a wide, kidney-shaped chamber, ultra-modern in its decoration and furnishings, and equipped with a bar. Around the long arc of the lounge there are to be glassed-in cases in which sponsors of exhibits in the Hall of Medical Science may make displays of their products.

Membership in the Professional Club is open to all accredited members of the American Medical Association and the American Public Health Association. All told, 300,000 members of national organizations in the medical and public health field will be eligible for professional membership in the club. In addition to physicians and surgeons, membership has been extended to dentists, health workers, pharmacists, veterinarians and nurses. Professional memberships will carry no dues, and the facilities of the club will be open only to professional members and accredited representatives of participating organizations whose financial support made possible educational exhibits in the building.

WEST VIRGINIA JOINS THE PROCESSION

ON February 27, West Virginia became the 11th state passing a measure which requires a doctor's certificate showing that neither applicant for a marriage license has syphilis in an infectious stage. The law goes into effect in 90 days.

It was sponsored by the West Virginia State Department of Health and endorsed by the Federation of Women's Clubs as well as the State Medical Society, State Nursing groups, State Conference of Social Work and the State Parent-Teachers Association. The bill is stated to have been opposed by a lobby of taxi-cab drivers and clergymen from West Virginia's Gretna Green.

1938 HEALTH CONSERVATION CONTESTS NEAR COMPLETION

THE Grading Committee will meet on April 12, to decide the awards to be given for the 1938 City Health Conservation Contest, the Rural Health Contest in both the United States and Canada, and the special competitions for programs designed to combat tuberculosis and syphilis. This year completes the tenth annual city contest, and the fifth rural contest.

Carl E. Buck, Dr.P.H., has stated that these annual health contests, conducted by the United States Chamber of Commerce in coöperation with the American Public Health Association, constitute the most effective tool thus far devised for stimulating active and intelligent lay interest in the furtherance of sound health protection and promotion services throughout the country. While the returns are still incomplete, it is certain that the 1938 results will be considerably in advance of those of preceding years. It has been estimated that the increase in effective participation in the rural counties will amount to approximately 40 per cent over the preceding year. The public press will carry the announcement of this year's reports on or about April 18.

GOVERNMENTAL INDUSTRIAL HYGIENISTS CONFERENCE

THE Second Annual Conference of Governmental Industrial Hygienists will take place immediately following the State and Territorial Health Officers meeting, and will extend over a 3 day period, April 26-28. It will be held in the Public Health Service auditorium, Washington, D. C.

PERSONALS

Central States

WILLIAM E. BUNNEY, PH.D.,* Director of the Biologic Products Division

of the Michigan State Department of Health, Lansing, for seven years, has resigned to become Director of Biologic Products for E. R. Squibb & Sons, New Brunswick, N. J.

Eastern States

VIVIAN DRENCKHAHN, M.S., C.P.H.,† who for several years has been health teaching consultant of the Buffalo Tuberculosis Association, New York, has resigned to accept a position in health education sponsored jointly by the Kellogg Foundation and the University of Michigan. Her work will be limited to the 7 county area served by the Foundation, and will include courses for teachers-in-service, curriculum construction work and special studies among children, under the direction of HENRY J. OTTO, PH.D., of the Kellogg Foundation.

DR. JOSEPHINE EVARTS, of Cornwall Bridge, Conn., has been appointed Health Officer of Kent, Conn.

DR. WALTER S. LAY has been appointed Health Officer of Hamden, Conn.

RAYMOND E. LEACH,* Bacteriologist in charge of the District Public Health Laboratory, Kansas State Board of Health, Parsons, Kans., has resigned to accept a position in the laboratory of the Cattaraugus County Department of Health, Olean, N. Y.

FREDERIC W. NORDSIEK † has resigned as Executive Secretary of the New York Diabetes Association, a position he has held on a part-time basis since last April when he became Associate in the Department of Nutrition of the American Institute of Baking, New York, N. Y.

LAURA M. LONG RIEGELMAN, M.D.,† for the past 19 years Chief of the Bureau of Child Hygiene in Brooklyn, N. Y., retired December 31, after 40 years of service with the New York City Department of Health.

THOMAS M. RIVERS, M.D.,† of the Rockefeller Institute for Medical Research, has been appointed a member of the Board of Health of New York City.

DR. REUBEN ROTHBLATT has been appointed Acting Health Officer of Willimantic, Conn., succeeding DR. NATHAN M. SPECTOR, resigned.

DR. HOWARD G. STEVENS, of New Milford, has been appointed Health Officer of Sherman, Conn.

HELEN STACEY has been appointed as Nutrition Consultant for the Henry Street Visiting Nurse Service. Miss Stacey served as Nutritionist for the American Telephone and Telegraph Company for the past 10 years and was responsible for the development of a nutrition program for the women employees of the Bell System. She has also served as Nutritionist for the American Red Cross and the Association for Improving the Condition of the Poor of New York City.

* Fellow A.P.H.A.

† Member A.P.H.A.

DR. PAUL I. YAKOVLEV, of Waltham, Mass., has been appointed Clinical Director of the Walter E. Fernald State School, Waverley.

Southern States

WOFFORD E. BALDWIN, M.D.,† formerly Health Officer of Chester, S. C., has been transferred to Oconee County, with headquarters at Valhalla.

WILLIAM H. BALL, M.D.,† of Tampa, Fla., has been appointed Director of the recently organized health unit in Franklin and Gulf Counties.

DR. WILLIAM B. BONES, formerly of Monteagle, Tenn., has been appointed Associate in Charge of the Division of Child Hygiene of the Alabama State Department of Health.

DR. HENRY BRANDON, of Yadkinville, N. C., has been appointed Health Officer of Yadkin County, succeeding DR. LOCKSLEY S. HALL.

DR. HERBERT E. CANNON, of Covington, La., has been appointed in charge of a new health unit to be established in St. Tammany Parish.

DR. ROBERT A. CLANTON, of Grenada, Miss., has been appointed Health Officer of Grenada County, succeeding the late DR. THOMAS J. BROWN.

DR. THOMAS W. COLLIER, of Lyons, Ga., has resigned as Health Commissioner of Toombs County, to engage in private practice in Port Arthur, Tex.

JOSEPH RIGNEY D'AUNOY, M.D.,† of New Orleans, La., has been appointed by the Louisiana State University Medical Center to serve as a member of the board of the Guidance Center of the New Orleans Institute of Mental Hygiene.

DR. LITTLETON H. EUBANKS,† of Lexington, Miss., Assistant Health Officer in Lauderdale County, Miss., has

been appointed in charge of the unit in Holmes County.

DR. ROBERT B. C. FRANKLIN, of Chapel Hill, N. C., has been appointed as Health Officer of Surry County, succeeding RALPH J. SYKES, M.D., resigned.

DR. THOMAS H. D. GRIFFITTS,† Director of the Henry R. Carter Memorial Laboratory of the U. S. Public Health Service, Savannah, Ga., has been appointed Acting City Health Officer.

DR. BENJAMIN F. HAND, JR., of Greenville, Miss., has been appointed Health Officer of Washington County.

GEORGE H. HAUSER, M.D.,† of New Orleans, La., has been appointed City Bacteriologist, succeeding the late WILLIAM H. SEEMANN, M.D.†

DR. JOHN H. HINES, of Atlanta, Ga., has been appointed Assistant Health Officer of Lauderdale County, with headquarters at Lexington, Miss., succeeding DR. LITTLETON H. EUBANKS.†

DR. WILLIAM H. KAEISER, of McAlester, Okla., has been appointed Health Superintendent of Pittsburg County.

NORRIS C. KNIGHT, M.D., C.P.H.,* of Clarksdale, Miss., has resigned as Director of the Coahoma County Health Unit, to take charge of the unit in Lauderdale County, with headquarters in Meridian.

ALBERT McCOWN, M.D.,† former medical director of the maternal and child health division of the Federal Children's Bureau, has been appointed Deputy Commissioner of the Michigan State Department of Health, effective February 1. Dr. McCown will direct the local health services of the department, aiding in coördinating the activities of the full time health departments and promoting the establishment of similar departments in the 24 counties not yet providing this service.

* Fellow A.P.H.A.

† Member A.P.H.A.

ROBERT S. MCGEACHEY, M.D.,† of Waldon, N. C., has resigned as Health Officer of Halifax County, to go to Craven County.

JOSEPH A. MORRIS, M.D.,† of Oxford, N. C., has resigned as Health Officer of Granville County, where he has served since 1919.

DR. THOMAS LON OWINGS, of Poplarville, Miss., is Acting Health Officer in Pearl River County, to relieve RANSOM J. JONES, M.D.,† Health Officer, who is on leave of absence for study at Johns Hopkins University, Baltimore.

DR. HENRY R. PERKINS, of Rockmart, Ga., has been appointed Health Officer of Abbeville and Laurens Counties.

DR. MAURICE C. PINCOFFS, Professor of Medicine at the University of Maryland and Instructor in Medicine at Johns Hopkins University, has been appointed a member of the Maryland State Board of Health. He succeeds DR. JOSEPH IRWIN FRANCE, who died recently.

GUY R. POST, M.D.,† of Holly Springs, Miss., Health Officer of Marshall County, has been appointed Director of the Coahoma County Health Unit, succeeding NORRIS C. KNIGHT, M.D., C.P.H.,* resigned.

BENJAMIN M. PRIMER, M.D.,* of Austin, Tex., has been appointed Director of the Travis County Health Unit, to succeed BOLIVAR J. LLOYD, M.D.,† resigned.

DR. DUDLEY A. REEKIE, of Louisville, Ky., Field Director of County Health Work in Kentucky, has been appointed Assistant City Health Officer of Atlanta, Ga.

MACK I. SHANHOLTZ, M.D.,† former health officer with the Health Unit in Bristol, Va., is now Director of the Commonwealth Fund Health

Unit located in Seminole County, Okla.

DR. MURPHY M. SIMMS has been appointed Director of the Vermilion Parish Health Unit, Abbeville, La., succeeding DR. BENJAMIN O. MORRISON,† who was assigned as Director of the Acadia Parish Unit, with headquarters at Crowley.

DR. JOHN W. SPIES has been appointed Dean of the University of Texas Medical School and Professor of Public Health. Dr. Spies was formerly instructor in surgery and pathology at Yale University and associate professor of surgery at Peiping Union Medical College.

RALPH J. SYKES, M.D., has been appointed health officer for Halifax County, N. C.

K. L. K. WAERING, M.D., formerly Director of Hadsden County, Florida, has been appointed to take charge of the Duval County Health Unit, with headquarters in Jacksonville.

WILSON C. WILLIAMS, M.D.,* Assistant Professor of Preventive Medicine and Public Health, Vanderbilt University School of Medicine, Nashville, Tenn., was recently reappointed State Health Commissioner.

Malnutrition—A Challenge and an Opportunity*

FRANK G. BOUDREAU, M.D., AND
H. D. KRUSE, M.D.

Milbank Memorial Fund, New York, N. Y.

THE title of our paper is taken from a paragraph in the report of a League of Nations Committee on the relation of nutrition to health, agriculture, and economic policy:

The malnutrition which exists in all countries is at once a challenge and an opportunity; a challenge to men's consciences and an opportunity to eradicate a social evil by methods which will increase economic prosperity.¹

We may not be directly concerned with the economic effects of our work, nor with its relationship to the campaign for social justice. Nevertheless it is inspiring to consider that in our efforts to deal with a serious health problem, we may be helping to bring about in this troubled world, greater and more widespread economic prosperity, and aiding in the eradication of one important cause of social unrest.

LAG BETWEEN SCIENTIFIC ADVANCES AND THEIR APPLICATION

Public health work has made great progress in the last fifty years because trained men and women have devoted their lives in the laboratory and the field to the study of its problems, adding little by little to our stores of knowledge. Too often the application of new knowledge for the benefit of the mass has been long delayed. The forces of inertia have perpetuated the use of technics and methods of work long after the addition of new knowledge should have rendered them obsolete, and public health programs are planned all too frequently by individuals who ignore the fact that our knowledge of problems and technics and our resources and equipment have advanced with the years.

The promotion of nutrition is a case in point. The great advances in the science of nutrition during the last 25 years have been applied only sparingly. The tax supported agencies entrusted with the care of the public

* Read at a Joint Session of the Child Hygiene and Food and Nutrition Sections of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 25, 1938.

health have been in this respect the victims of inertia and tradition. Methods used by the health and school authorities to detect malnutrition and to promote nutrition are very much the same as those applied a quarter of a century ago, and the problem remains vague and ill defined. Social agencies other than the health and school authorities have recognized the importance of a more precise knowledge of the problem and have attempted to apply to it the newer methods developed in the laboratories of biochemistry and physiology. The result is that we do not look to health agencies for advice and help on nutrition problems but to home economists and dietitians, the agricultural schools and land-grant colleges, and universities. These individuals and institutions deserve every credit, and their efforts should be encouraged by every possible means, but their partial capture of this important section of the public health field should not mean avoidance of responsibility by the health agencies.

METHODS OF APPRAISING NUTRITIONAL STATUS AT PRESENT IN USE

Let us subject the statement of the League's committee that malnutrition exists in all countries to some analysis. Certainly cases of pellagra, rickets, scurvy, and beri-beri still occur in large numbers in many countries. Apart from these recognized deficiency diseases we have very little definite information on the extent of malnutrition even in the most advanced countries. For some years several methods of arriving at estimates of the number of malnourished in any group have been at our disposal. First we may study the availability and cost of the foods required for an adequate diet within a community. This however ignores differences in dietary habits of the individuals forming the group. To avoid this error, dietary studies of

families and individuals may be made. While these are difficult and costly, they do yield information of value if properly carried out, but of limited value because the individual's state of nutrition does not depend solely on his diet. Another approach has been by way of anthropometric measurements. The deficiencies and limitations of this method have been described clearly in the literature.

Under another plan the adequacy of the diet is appraised by providing extra supplies of protective foods to one group and noting the improvement in height, weight, and physique of that group as compared to a control group.

The clinical examination is another common method of appraising nutrition. The results in this case depend so much on the individual's judgment based on his appreciation of a number of variable factors that, taken alone, it is of limited value for public health use. The fact that the results of the appraisal of identical groups by different clinicians often differ widely is a sufficient criticism.

While some of these methods require perfecting, and others provide only limited or indirect evidence of malnutrition, it would seem that there has been available in the past a series of methods which should have given a rough idea of the extent of the problem of malnutrition in the advanced countries. What use has been made of these methods to define the problem of malnutrition in this country?

EXISTING EVIDENCE OF MALNUTRITION IN THE UNITED STATES OF AMERICA

During the 4 years 1926-1930, surveys were conducted on the dietary habits of families in rural areas in 6 different states; all revealed varying amounts of undernourishment.² During the past 5 years this type of study has constantly shown nutritional impairment among a definite proportion

of the urban population. For example, in one survey³ among 748 low-income families, 21 per cent were found to be receiving diets with an average energy value more than 25 per cent below the accepted standard; while for an additional 25 per cent of the families, the caloric intake was 10 to 25 per cent too low. From the standpoint of diets low in certain essentials, the proportion of families was even higher.

Figures of substantially the same order were obtained in another survey⁴ by use of a different technic. Records of food consumption were collected by the U. S. Bureau of Labor Statistics, and the nutritive content of the diets analyzed by the Bureau of Home Economics. Of 897 families of employed workers, only 29 per cent had "Grade A" diets, while 45 per cent had "Grade B," and 26 per cent "Grade C" diets. "Grade A" diets provided "a generous margin of safety in all nutritional essentials"; "Grade B" diets met average minimum requirements with an uncertain margin of safety; while "Grade C" diets failed in one or more respects to meet average minimum requirements. One would expect to find among these families a large number of malnourished individuals in the 26 per cent ("Grade C") group, and a smaller number in the 45 per cent ("Grade B") group. Nearly 90 per cent of the Negro families in this study consumed "B" or "C" diets; the percentage was 70 among white families. This is evidence that there has been a serious nutrition problem in the areas (Pacific, Southern, and North Atlantic cities) in which those families live; it is not precise enough to enable us to select for attention the individual victims of malnutrition.

During the past 5 years at least 10 studies have demonstrated the beneficial effects of supplemental foods in

the diets of children, with the obvious inference that the previous dietary was inadequate. One such study⁵—the most recent—on 150 children for 1 year showed that those receiving a supplement made greater progress during the period of observation.

There have been numerous clinical studies of children to determine their state of nutrition. Roberts⁶ summarized 13 such investigations carried out between 1906 and 1924, each covering thousands of children. The average percentage adjudged by clinical evidence to be suffering from malnutrition was 22.3. In 1932 the Community Health Center in Philadelphia with an annual medical case load of almost 2,000 cases reported malnutrition among 35 per cent.⁷ In 1933 one-third of several hundred children in New York City were rated by clinicians as "poorly" or "very poorly" nourished.⁸ Among 28,000 white children from 6 to 15 years of age examined in 21 states from 1928 to 1932, 6 per cent were stated to be malnourished by clinical examination without reference to any standards of height and weight.⁹

In 17 investigations carried out between 1918 and 1924 with the weight-height ratio as a criterion of nutritional status, 32.7 per cent of the persons examined were adjudged to be malnourished.¹⁰ We may be sure that many malnourished children escaped this screen while a considerable number of well nourished were included. Of 5,000 white children from 6 to 9 years of age, examined during 1929 to 1933 in 6 widely scattered cities, 43 per cent were below their age and sex-group average in weight.¹¹ It should be borne in mind that the statistical averages so determined may not represent the desired standard since 22 per cent were well above this level.

The fact that some 4,000 persons are recorded as dying of pellagra every year in the southern states of this

country is further objective evidence as to the state of public nutrition.

IMPORTANCE OF RAISING STANDARDS

It is to be noted that most of the standards used in these studies relate to average or minimum requirements while modern teaching suggests that we should relate nutrition appraisal to optimum standards. We believe that the area between minimum and optimum requirements will become of increasing importance in future work on nutrition. Minimum requirements are those which prevent signs of nutritional deficiency detectable by the ordinary methods in common use. It is more than probable that there are signs of nutritional deficiency which escape attention at present but which the use of the new methods of appraisal will enable us to discern. Our aim should be not mere existence at just above the level of detectable nutritional deficiencies, but that abounding health and vitality for which human beings have hungered throughout the ages.

A number of leading nutrition experts have expressed the belief that the greatly increased use of the protective foods may constitute a means of attaining greater vitality and possibly longer life. The reported experiments of Sherman seem to point in that direction.

THE LATENT STATE

By analogy with known disease entities, we should expect to find a latent period before certain states of malnutrition declare themselves frankly. It is also probable that in the majority of instances these latent states may clear up with time. It might be argued that nothing need be done about them; but two considerations must be borne in mind. First, experience teaches that the best time to deal with any condition affecting the health of the individual is in its earliest stage, before it has

done any permanent damage. Second, if our standards are to provide a safe margin above the minimum, and if we would strive for abounding health rather than for a so-called normal existence on the lowest or average level, we cannot afford to neglect these latent states of malnutrition.

It will be noted that we regard the improvement of nutrition as a medical problem, and the detection of latent states of malnutrition as one of the most important tasks of health agencies. The introduction of precise and objective methods offers a fresh opportunity of appraising nutrition. In what measure are we equipped to carry out that task? In recent years the science of nutrition has so advanced that certain of its contributions are ready for practical application. For example, at least 5 of the vitamins, and in some instances their precursors in the human body, have been isolated; their chemical and physiological properties have been demonstrated and suitable chemical and physiological tests have been worked out, whereby the latent state in several deficiency diseases may be recognized. Many of these tests are being used currently in hospital and dispensary practice, where they have opened the way to new fields of knowledge and to more effective therapy. Disturbances of nutrition are associated with practically every disease to which flesh is heir, and these new methods are helping to define the character and importance of this part of the symptom complex.

At the last Annual Conference of the Milbank Memorial Fund, a distinguished group of clinicians, biochemists, pediatricians and physiologists, was called together to report on these tests. We quote from their report¹²:

Diagnostic methods have been elaborated for detecting the early stages of the various specific deficiency diseases which are seen in the population, and these tests are in various stages of development. In general they fall

into two groups: physiological and biochemical. Physiological tests are used in detecting the latent state by applying an exaggerated stimulus or stress, and eliciting those signs which occur naturally in the more severe stages of the disease. The chemical tests are performed on the blood or urine where dietary inadequacies or other etiological factors are reflected by low values. Specific tests have been developed, or are in the process of development, for such nutritional disturbances as deficiency in vitamins A, B₁, C, D, protein and iron. (It should be explained that both types of tests have not been developed for all deficiency diseases; nor where they are available, are they developed to the same degree. In some, the physiological test is at the moment superior; in others the advantage rests with the chemical test.) In the opinion of the group, some of these tests have now been perfected to the point where they are ready for trial application to a much wider extent than has been given them in the past.

USE OF NEW PHYSIOLOGICAL AND BIOCHEMICAL TESTS

This is an extremely conservative statement and rightly so. There is no doubt that several of these methods are ready for immediate practical test on a large scale, but a period of trial application under experimental conditions would seem to be a desirable safeguard against the indiscriminate use of any methods not completely developed, and against piecemeal utilization of any one method as sufficient in itself for assessing nutritional status. Just how many tests are reliable enough for routine use, how many should be used, and how they may be used most effectively, are as yet unanswered questions. For routine application in public health work, where large numbers must be dealt with, and where there are limitations in budget and personnel, the specific questions are: How *few* of these tests will give a reliable indication of nutritional status; and how may these tests be applied to large groups as effectively and economically as possible?

Scattered attempts are being made, largely under the leadership of uni-

versity departments of home economics, to answer these questions. A comprehensive study is being planned on a coöperative basis by the Departments of Preventive Medicine and Pediatrics of Cornell University, the U. S. Public Health Service, the New York City Department of Health, and the Milbank Memorial Fund.

Plans under consideration call for medical as well as dietary histories of a large group of children. In the medical history more than the usual emphasis will be placed on the occurrence of infections, amount of sleep, amount and type of activity, and exposure to sunlight.

The physical examination will include selected measurements and be supplemented by a dental examination. Among the physiological tests will be measurement of visual dark adaptation and the neuromuscular response to galvanic stimuli. Roentgenograms will make possible a study of the skeletal system. Examination of the blood will include a red cell count, determination of the concentration of hemoglobin, an hematocrit reading of the proportion of corpuscles, a total and differential white cell count. Biochemical tests will be used to measure the concentration of ascorbic acid, calcium, phosphorus, and phosphatase in the blood. The thorough clinical examination will be supplemented by stethographic and electrocardiographic recordings of the heart sounds and conduction patterns. Urine examinations for sugar and albumin will be carried out. Finally, there will be a serological test for syphilis and a Mantoux test.

This is an extraordinary number of tests to apply to a population, and we do not believe that it will be practicable widely to generalize such studies. This is essentially an experimental study with the object of selecting those tests and methods which may be recommended for routine use in appraising

nutritional status. The task we have undertaken is difficult and time consuming, and our results will need confirmation by other workers. We wish to emphasize that the ultimate object is to determine the size, the nature, and the distribution of the nutritional problem. Such knowledge is essential if we are to raise the nutritional level of our people. Without accepted methods of ascertaining the individual's state, the nutrition work now being carried on cannot be sharply focused on the malnourished. For lack of such methods the results of the educational work in nutrition, on which much time and money are being spent, cannot be closely evaluated. Finally, the absence of such methods makes it difficult to supplant debate by demonstration on whether, or to what extent, impaired nutrition may play a part as a predisposing factor in parasitic diseases, such as tuberculosis; as well as the part played by satisfactory nutrition in building up resistance against such disease.

THE CHALLENGE TO THE OFFICIAL HEALTH AGENCIES

If the League's committee is correct in its view that the malnutrition existing in all countries is a challenge and an opportunity, that challenge and that opportunity are of the greatest importance to the health agencies, for to them has been entrusted the care of the public health. We have suggested that these agencies have been somewhat handicapped by tradition and have failed to advance as rapidly as increasing knowledge of nutritional science would appear to permit. The opportunity presented by malnutrition has been seized by other social agencies which are attempting to apply for public benefit the newer knowledge of nutritional science. We cannot place obstacles in the path of any agency which is doing good work in this field,

but we can review our own position, adapt our own program to the new knowledge and the new opportunities and join with these other agencies in the attempt to use the new weapons of science in the cause of greater social progress. The U. S. Public Health Service has set a splendid example by its recognition of the importance of nutrition in the public health field. It has helped to advance our knowledge of the science, and carried out critical studies of the means now used to apply that knowledge. Nor has the U. S. Children's Bureau failed to appreciate the importance of the factor of nutrition in infant and maternal welfare.

We believe that the American Public Health Association is in a position to provide at least some of the leadership needed by the public health agencies in their effort to meet the challenge of the widespread existence of malnutrition. It is our earnest hope that the challenge will be met and the opportunity seized as rapidly and adequately as possible.

Knowledge and Wisdom

"Man has grown exceedingly powerful. . . . He has gained in knowledge and skill at a rate which in modern times can be likened only to the ascent of a skyrocket. . . .

Thus we have grown marvellously powerful and clever in our means for achieving our purposes. But in the wisdom of our choice of purposes to be achieved we have at best marked time; when, with the advancement of our powers for good and ill, the problem of adjusting our standards of value to the new conditions has become superlatively urgent.

We may well ask: Has an immature

human race stumbled upon a dangerous toy? Are we children playing with a loaded gun? Shall we grow up in wisdom before tragedy engulfs us? Is this the riddle of the Sphinx, to fail in which means destruction? Or may we perhaps look forward to an era of an awakening in wisdom, commensurate with the rocket-like ascent in knowledge? Should this come about, then Utopia, from an idle dream, would become a real presence." — Alfred J. Lotka, Contact Points of Population Study with Related Branches of Science. *Proc. Am. Philosophical Society*, Feb. 15, 1939, p. 624.

A Comparison of Indices Used in Judging the Physical Fitness of School Children^{*†}

SUSAN P. SOUTHER, M.D., MARTHA M. ELIOT, M.D.,
AND RACHEL M. JENSS, Sc.D.

*State Department of Health, Hartford, Conn.; and U. S. Children's
Bureau, U. S. Department of Labor, Washington, D. C.*

WITH the public conscience demanding protection of the health of the child and the school medical services expanding to meet this need, the development of a simple, economical, but accurate means of assessing the child's state of well-being or physical fitness is in order. During recent years many workers in the field of child health and growth have recommended different indices of body build as a step in the solution to this problem. Clinicians have recognized that the use of such an index is only one of the tools at their command for evaluating the individual child's state of well-being, and that the child's past history, his individual growth pattern, the evidences of nutritional deficiencies, such as rickets or anemia, as well as of organic disease, are also of significance. But such a highly refined examination, including laboratory procedures, is not

practical in the ordinary school health program, so that there is a need to determine which of the various methods of assessment may be both easy to apply and productive of results.

To help clarify this situation the U. S. Children's Bureau, the Institute of Human Relations, and the Department of Pediatrics of the Yale University School of Medicine undertook a study of 713 seven year old white boys ‡ and girls living in New Haven, Conn., during 1934-1936.** The primary objective of this investigation was to study and compare various procedures used in evaluating the child's health. A full and detailed report is in preparation at the present time. This paper is concerned only with a limited aspect of the whole problem; namely, the ability of each of four indices of body build to identify children who are likely to be physically unfit, using as criteria of reference (1) the findings of the physician with respect to the child's general nutritional condition, and (2) the child's annual rate of gain in weight.

* Read at a Joint Session of the Child Hygiene and Food and Nutrition Sections of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 25, 1938.

† From the Children's Bureau, U. S. Department of Labor, with the coöperation of the Institute of Human Relations of Yale University, and the Department of Pediatrics of the Yale University School of Medicine. Grateful acknowledgment is made to Frank K. Shuttleworth, Ph.D., for assistance in planning and directing the study.

‡ Age is defined in completed years last birthday.

** The children were first examined when they were 6 years old, but the analyses are based on the observations made when these boys and girls were 7 years of age.

This study has one particular advantage: All the indices have been applied to the same group of children, and probably for the first time there are available direct comparisons of the ability of the several indices to identify boys and girls who may be in need of medical attention or nutritional assistance. The indices studied include, first, the Baldwin-Wood height-weight index; second, the Pryor width-weight index, which is an elaboration of the Baldwin-Wood standard; third, the Nutritional Status Indices developed by Franzen and his coworkers in the American Child Health Association; and fourth, the ACH (arm-chest-hip) index, which was also developed by that group.

The assumptions inherent in the development of such indices of body build and the applicability of the statistical methods used in deriving the indices and identifying children who may be in a poor physical condition deserve careful consideration. It is also important to know the kind and number of children whose measurements were used in forming the indices. All these problems are important, but the school health officer is primarily interested in knowing whether an index works; that is, whether it is able to pick out children who may be physically unfit. The New Haven study attempts to answer this question in respect to 7 year old children.

In applying and testing these four indices, the prescribed procedures as laid down in the original reports have been followed. According to the Baldwin-Wood index a child less than 10 years of age is underweight if his actual weight is 6 or more per cent less than his expected weight. The Nutritional Status Indices of Franzen make it possible to determine a child's standing, relative to his skeletal peers, in each of three "traits"—arm girth, weight, and subcutaneous tissue. As

Franzen has not indicated the percentage of children who are likely to be physically unfit, each index has been set to identify, for the purpose of this study, the lowest 15 per cent of the boys and girls.* The children thus selected have been defined arbitrarily as the group most likely to be in need of medical care or nutritional assistance. A similar procedure for identifying the lowest 15 per cent of the children has also been employed in the New Haven Study for testing the Pryor width-weight index,† while the ACH index has been set to pick out the lowest 14 per cent of the group of boys or girls included in the study.

All white children who were of single, legitimate birth, who were between 6 and 7 years of age when the first physical examination was made, and who were attending the public or parochial schools of New Haven, Conn., were eligible for inclusion. A single pediatrician made two annual physical examinations of each child. At the same time a single technician trained in anthropometry took the necessary anthropometric measurements according to the prescribed technics. The child's medical history and his socio-economic status were ascertained, and he was weighed at quarterly intervals during the 19-20 month period of observation. Except for hemoglobin and red blood cell tests of 133 of these children, no attempts were made to refine the clinical examinations with laboratory tests of the child's physiological state.

A single case history may serve to illustrate the different kinds of observations which were made on each child.

J. K. was a little Polish girl who lived with her mother and an older brother and sister

* Table X, *Nutritional Status Indices*, p. 65. American Child Health Association. New York, 1935.

† The method has not been outlined in any of Dr. Pryor's papers, but she has approved this procedure, which corresponds approximately to the method used in testing the Nutritional Status Indices.

in the central part of New Haven. The family income was very low both years of the study—only about \$545 when J. K. was 7 years old. The child's diet was necessarily poor in amount and quality. Vegetables, fresh fruit, and meat were served about twice a week, eggs even less frequently. On the other hand, J. K. usually had two to three cups of milk a day. She regularly attended the infant and child health conference in New Haven until she was 2 years old. Her medical history was negative except for whooping cough at 3 years of age.

This little girl was relatively small for her age. At 7 years she weighed about 7 pounds less than the average girl included in the study, was 1 to 2 inches shorter, and more than 1 centimeter narrower at the hips (bitrochanteric width). Her weight gain between the two physical examinations was very unsatisfactory. Between 6 and 7 years of age she gained less than half as much as the average girl included in the study.

According to the physician's judgment she was poorly nourished at the time of both annual physical examinations. The most important clinical findings included the following items: The amount and condition of the child's subcutaneous fat and musculature were recorded as poor at both 6 and 7 years of age; the two 6 year molars which erupted in the interval between the physical examinations as well as the two which had erupted earlier were all carious when the second examination was made. There was also a moderate deficiency in hemoglobin (84 per cent),* and a somewhat lowered red-blood count (4,240,000).

The child had several illnesses during the period of observation. She had measles 4 months after the first examination was made, and just before the second examination she suffered from an acute upper respiratory tract infection and a rather severe gastrointestinal upset.

The question before us is then: Do the indices indicate that this child was in a poor physical condition at 7 years of age? She was identified as under par by the Baldwin-Wood index. According to this index she was found to be about 7 per cent underweight, but the Pryor width-weight index and the ACH index failed to identify her as below

par. The Nutritional Status Indices of Franzen indicated that both her subcutaneous tissue and weight were within normal limits but that her arm girth was much smaller than would have been expected (86 per cent of the girls with the same body build would have had a larger arm girth). Of course, these results should be interpreted cautiously in so far as the child's well-being is concerned, for it should be remembered that none of the indices or tables attempts to evaluate physical fitness as such but only in so far as it is related to such measures as the child's weight, arm girth, subcutaneous tissue, or the difference between arm girth and chest depth estimated in terms of body build as defined by each index. It should also be pointed out that these findings are of interest only in reflecting the ability of the indices to evaluate this particular child's physical condition.

The more important question whether the indices identify the majority of the children who are physically unfit can be answered only by comparing each of the four indices with other criteria of physical fitness. For example, the boys and girls whom the physician judged to be poorly or very poorly nourished at 7 years of age were compared with the children who were identified by an index as likely to be in a poor physical condition. Similarly, the boys and girls who exhibited an unsatisfactory percentage weight gain between 6 and 7 years of age were compared with the children who were selected by each index. Other and even more restricted criteria, involving both clinical judgment and estimates of gain in weight or increase in arm girth, also were applied.

In this preliminary report it is possible to present only two comparisons. The first concerns the agreement between the physician's clinical judgment and each of the indices. The physician

* The Haden-Hauser hemoglobinometer was used for estimating hemoglobin. These determinations were made 17 weeks following the second physical examination.

who examined these children classified 40 of the 348 girls as poorly nourished at 7 years of age. The Baldwin-Wood index identified 25 girls, or 63 per cent of these 40 children, as underweight. When the Pryor width-weight index was applied only 28 per cent of the 40 girls were picked out as underweight, and with the ACH index the percentage identified as below par was apparently somewhat less (10 per cent). The results of testing the Nutritional Status Indices of Franzen appear to be even more discouraging. The weight index identified only 3 per cent, and the indices for arm girth and subcutaneous tissue picked out 5 per cent of the 40 girls whom the physician judged to be poorly nourished at 7 years of age. Although these percentages are based on a very small number of children, it should be remembered that according to one physician's judgment these 40 girls represent the more extreme cases of poor nutrition. Although her clinical judgment is liable to a certain amount of error, is it not reasonable to expect that even for such a small number of children there would have been better agreement between the clinical judgment of the child's general nutritional status and any one of the indices if the physician and the index were each attempting to measure the same phenomenon?

The second comparison is between annual percentage gain in weight—a more objective criterion than clinical judgment—and each of the indices applied when the children were 7 years of age. Assuming that the children who exhibited an unsatisfactory percentage gain in weight (those in the lowest 10 per cent of the group) were likely to be in a poor physical condition, the results, so far as showing the usefulness of any of the four indices, are even more discouraging. The percentage of such children identified by any one of the indices is very low. The

Baldwin-Wood index showed the maximum agreement, only 29 per cent, while the Nutritional Status Index for weight failed to identify any of the 35 girls whose weight gain was considered very unsatisfactory. Here again the results should be interpreted cautiously, for the percentages are based on only 35 children. It should be remembered, however, that their weight gain was exceeded by 90 per cent of the girls who were included in the study.

These findings pertain only to the girls.* Similar analyses indicate that the indices also failed to identify a large number of the boys whom the physician judged to be poorly nourished or whose weight gain was markedly below average.†

Of course neither of these two criteria—clinical judgment and the child's percentage gain in weight—is an entirely satisfactory method for assessing the total physical well-being of the child. This does not mean, however, that they cannot be used to furnish evidence for judging the validity of the indices. On the contrary, one may expect that a large proportion of the children who are selected by these criteria should also be identified by the indices.

* The evidence presented in this paper may be substantiated by ascertaining the percentage of the 348 girls who must be identified by each index (except the ACH index which does not permit of such an analysis) in order to include the 40 girls whom the physician found to be poorly or very poorly nourished. These percentages are as follows: For the Baldwin-Wood index, 79.5 per cent; the Pryor index, 81.8 per cent; the Nutritional Status Index for weight, 89.0 per cent, for arm girth, 84.1 per cent, and for subcutaneous tissue, 93.1 per cent.

The percentages for including the 35 girls whose weight gain was unsatisfactory are 98.6 for the Baldwin-Wood index; 97.7 for the Pryor width-weight index; 98.6 per cent, 100 per cent, and 97.7 per cent, respectively, for the Franzen weight, arm girth, and subcutaneous tissue indices. Thus it is necessary to set the Pryor index to identify 97.7 per cent of the 348 girls in order to include the 35 girls who showed an unsatisfactory weight gain.

† If the ACH, Pryor, and Nutritional Status Indices are set to identify the lowest 20 per cent instead of the lowest 15 per cent of the children, the agreement between the indices and each of the two criteria, clinical judgment and gain in weight, is also unsatisfactory.

If such indices do not furnish the school health officer with a satisfactory method of identifying a child who may be in need of medical attention or nutritional assistance, what procedures should he use? At the present time the clinical examination must certainly form an integral part of the assessment, especially if determining the need of medical care is to be one of the objectives of a school health program. On the other hand, a great deal can be done to improve the clinical examination and to make the physician's judgment more stable and objective. Provision must also be made for observing the child at regular intervals so that his physical condition can be evaluated in terms of his own previous growth and health. Until the physician is furnished with more satisfactory and practical tools for evaluating the child's physical fitness, it may also be wise to

supplement the clinical examination with some simple measure of the child's progress, such as his relative gain in weight. Observations made on the 713 children included in this study are being used to investigate this problem.

SUMMARY

Four indices—the Baldwin-Wood index, the ACH and Nutritional Status Indices of Franzen, and the Pryor Width-Weight index were applied to 713 seven year old boys and girls, who were observed for a period of 19 to 20 months in New Haven, Conn., during 1934-1936. The indices failed to identify many New Haven children whom the physician found to be poorly nourished or who exhibited a very unsatisfactory percentage gain in weight. A more comprehensive and detailed report of this study is in the process of preparation.

A STUDENT has unusual opportunities to court instruction during a visit with the college physician, whether the purpose of his call be for diagnosis or treatment of a specific ailment or for medical advice on some general problem, or because of some difficulty with the administration or some emotional value. In the doctor's office or infirmary the student is exposed to other situations which have distinct educational value. He should learn the methods of a well equipped

physician working in a "model" office. He should learn something of the doctor's problems of diagnosis and therapy, he should learn what to expect of medical procedures and the value to him of seeking early medical attention. He should learn something about the use and abuse of drugs, and should learn to interpret medical articles and advertisements. He should learn how to discriminate between sound and unsound medical practice.—C. E. Shepard, *Journal-Lancet*, Feb., 1939, p. 70.

Sanitary Condition of Paper Containers for Retail Packaging of Perishable Foods*

J. R. SANBORN

New York State Agricultural Experiment Station, Geneva, N. Y.

A STUDY has been made during the past two years of paper wrappers and containers for perishable foods. The work has included bacteriological studies of seven types of paper containers for milk and milk products, and a study of the sanitary condition of the paperboard out of which the containers are made.

IMPORTANCE OF CLEAN, SANITARY PAPERBOARD

As shown in Table I, paperboard made from mixed waste papers may yield bacterial counts of 1,000 to 40,000 colonies per gram. It is generally agreed that paper stock that has previously been used for commercial purposes should not be employed as packaging materials for perishable foods. High bacterial counts and the presence of miscellaneous foreign matter, dirt, ink, and waste in this secondary stock render it decidedly unsuitable for contact with foods. Food wrappers and containers should be made of virgin stock which may be processed and fabricated so as to yield

paper products that are essentially sterile.

In contrast to the class of materials containing secondary stock, this table also presents bacterial counts obtained from paperboard used for milk and other food containers. These were made entirely from virgin stock. The latter counts usually vary from essential sterility to 500 colonies per gm. Bacterial counts of paperboard consisting of virgin pulp have during the past year been steadily decreasing. The percentage of paperboard samples approaching essential sterility is on the increase.

The bacteriological results are obtained by reconvertng samples of paperboard under aseptic conditions, to pulp suspensions and analyzing the disintegrated paper. The device employed for this purpose previously described in detail¹ consists of a motor of the type used for food mixers, equipped with two fan-type beaters.† Bacteriological findings thus far indicate that paperboard having low bacterial counts yields containers which are nearly or actually sterile. While rinse tests may not reveal differences in

* Approved by the Director of the New York State Agricultural Experiment Station for publication as Journal Paper No. 301, December 10, 1938. Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 28, 1938.

† Arrangements are being made with the usual laboratory supply houses such as Fischer Scientific Materials Company, Pittsburgh, Pa., and the Will Corporation, Rochester, N. Y., to list this adapted equipment in complete form. Cost about \$20.

TABLE I

Bacterial Counts per Gram of Disintegrated Paperboard Obtained Between July, 1937, and October, 1938

Grades of Paper	Percent- age		Percentage Yielding Counts Between						
	Total	Showing							
	Number	No	51-100	101-250	251-500	501-1,000	1,001-10,000	10,001-40,000	
<i>Paperboard of Virgin Stock</i>									
Milk container board	824	5	30	26	21	10	8	0	0
Ice cream and butter boxes; cup, plate, cap stock	77	4	47	35	7	5	2	0	0
Paper straws	25	44	56	0	0	0	0	0	0
<i>Paperboard containing Secondary Stock</i>									
Fiber cans, breakfast food cartons, etc.	52	0	0	0	0	10	8	48	34

counts where a large majority of the containers give less than 5 colonies per container, the rinsing and incubation of containers with sterile broth is a useful method of determining the presence or absence of demonstrable organisms. This testing may be performed by introducing 10 cc. of sterile nutrient broth into each container, followed by shaking in the usual manner, but incubating the medium in the container. After incubation, containers are examined for the presence or absence of growth. Table II shows certain relationships of board counts and waxing

efficiency to container contamination.

The results of this investigation indicate that cleanliness and freedom from bacteria in paper containers for milk and milk products depend upon the use of a foundation board that is clean and free from bacteria, also the maintenance of this condition through proper methods of handling and storage. Efficient paraffining of high quality paperboard tends to suppress or "seal in" the few cells remaining in high class paper stock. Testing finished containers with sterile nutrient broth aids in revealing the effects of high

TABLE II

Correlations Between Bacterial Counts of Paperboard and Contamination of Finished Containers

Container Type	Source of Paperboard	Paperboard Counts Colonies per Gram	Number Containers in Series	Finished Containers		
				Percentage Sterile in Broth	Rinse Counts. Percentage Yielding Less than 5 Colonies per Container	Moisture Proofing
1	Mill A	Less than 100	1,003	77	96	Good
1	Mill I	Less than 250	2,335	14	93	Variable
2	Mill B	Less than 100	210	68	83	Good
2	Mill K	Less than 500	617	16	66	Variable
3	Mill G	Less than 500	695	16	73	Variable
4	Mill B	Less than 100	180	67	83	Variable

TABLE III

Influence of Temperatures of Paraffining on Bacteriological Tests of Finished Containers

Paraffining Temperatures	Number Containers in Series	Board Counts Colonies per Gram	Finished Containers		
			Rinse Counts		
			Percentage Sterile in Broth	Percentage Showing No Growth	Percentage Yield- ing Less than 5 Colonies
165° F.	730	Less than 250	82	66	96
180° F.	1,370	Less than 250	18	62	95

quality paperboard and efficient paraffining on the percentage sterility of the containers.

Over 90 per cent of the organisms isolated from container rinses were spore-formers and micrococci. The remaining types consisted of sarcinae, actinomyces, and filamentous fungi. This flora, which is typically heat-resistant and dryness-resistant, is characteristic of the organisms found in paperboard.

INFLUENCE OF EFFICIENT MOISTURE-PROOFING

The effectiveness of paraffin coating has a marked influence upon the results of bacteriological tests on fabricated containers. Where methods of paraffining produce continuous coatings of wax over paperboard surfaces with

effective sealing of corners, edges, and interstices, bacteriological findings show appreciable improvements over containers subjected to mediocre paraffining.

Table III indicates the significance of temperature, which is one of the factors influencing paraffining efficiency.

Generally speaking, more satisfactory coatings of wax were obtained at 165° to 170° F. than at temperatures of 180 to 185° F. Other factors, such as the physical properties of the sheet (porosity, smoothness of surface, formation, etc.) method of paraffining and draining, temperature of container before and after paraffining, and characteristics of paraffin used, also affect moisture-proofing efficiency. With the use of higher paraffining temperatures and slow cooling, while better penetra-

TABLE IV

Comparison of Results Secured with Four Different Rinse Methods Using Standard Nutrient Agar with Incubation at 37° C. for 48 Hours

Methods	Percentage		Total Number Containers Examined
	Showing No Growth	Yielding Less than 5 Colonies per Container	
Rinse 10 ml.			
8 ml. in 3 regular plates	48	92	1,561
8 ml. in 1 large plate	63	96	1,120
Rinse 20 ml.			
10 ml. in 3 regular plates	60	91	860
10 ml. in 1 large plate	64	94	770
			<hr/> 4,311

tion is usually secured than at lower temperatures, there is a tendency for excessive run-off of paraffin from side seams and from parts of containers having extra thicknesses of paperboard, leaving exposed uncoated areas which are capable of absorbing milk and other liquids. The primary purpose of moisture-proofing treatments of essentially sterile paperboard is to render the product non-absorbent. Paperboard specifications and paraffining procedures should be established which will result in efficient moisture proofing.

BACTERIOLOGICAL EXAMINATION OF PAPER MILK CONTAINERS' BY RINSE METHODS

Various rinsing and plating methods are under investigation. Table IV presents the results of plate counts obtained by rinsing one type of container with sterile water. This was a coöperative experiment in which 5 different laboratories, using the same methods and technic, participated.

Counts between 6 and 100 organisms per container are sometimes obtained and a few scattering ones that are over 100. The results presented in Table V show rinse counts obtained on 7 types of paper containers for milk, tested during 1937 and 1938.

During the present year marked improvements have taken place in the bacteriological condition of both paperboard and finished containers over the results obtained a year ago. Effective programs of cleanliness and microbiological control at pulp and paper mills and container factories are directly responsible for improved sanitary quality in containers for perishable foods. It is possible that the goal that the industry has set, namely, uniform sterility of paper products where these are used as containers and wrappers for perishable foods may eventually be achieved. In addition to paper containers, bottle caps, gaskets, and similar articles for milk and milk products, containers for ice cream, cheese, butter;

TABLE V
Rinse Counts Obtained from Various Types of Containers
Rinse Counts per Container During 1937 *Rinse Counts per Container During 1938*

Container Type	<i>Rinse Counts per Container During 1937</i>						<i>Rinse Counts per Container During 1938</i>					
	Total Number Examined	Percentage Showing No Growth	0-5	6-100	101-250	251-500	Percentage Showing No Growth	0-5	6-100	101-250	251-500	500+
1	4,787	43	88	10	1.5	0.14	0.36	57	93	6	0.93	0
2	1,523	9	85	10	1	0.7	0.3	31	76	20	2.0	0.4
3	1,299	0.5	13	80	3	1.4	2.6	22	70	27	0.7	0.3
4	180	34	83	15	0.3	0
5	70	37	87	12	1	0
6	120	18	71	27	2	0	0
7	74	12	60	36	4	0	0

These figures reveal only small differences among the rinse procedures used. As previously stated, however, where containers have so few microorganisms, it is helpful to supplement plating methods with a sterility test in which 10 cc. of sterile nutrient broth is added to each container.

and frozen foods; wrappers for bread, meat, butter, fruits and vegetables; also paper straws and trays are included in this investigation.

Specific and Nonspecific Serum Treatment of Scarlet Fever*

F. H. TOP, M.D., AND D. C. YOUNG, M.D.

Communicable Disease Service, Herman Kiefer Hospital and Division of Communicable Diseases and Epidemiology, Detroit Department of Health

THE serum treatment of moderately severe scarlet fever is common practice in communicable disease hospitals, and either convalescent serum or antitoxin is generally given by the intramuscular route. The usual dose for the former is 30 cc., and for the latter, one therapeutic dose (6-10 cc.). In some fever hospitals all patients with scarlet fever are treated with serum, and as a rule this is antitoxin. In others serum is administered intravenously whether it be convalescent serum or antitoxin, and although the therapeutic effect is somewhat better and more dramatic, still there is a hazard in such use. At the Herman Kiefer Hospital both sera are used. Prior to 1930 treatment was largely restricted to use of antitoxin, but since that time convalescent serum when available has largely displaced antitoxin because sensitivity to horse serum is thus avoided. There are proponents of both convalescent serum and antitoxin, but the literature reveals no studies carried out on large numbers of patients where both sera were used

during the same epidemic on alternate patients. Such a study was begun August 1, 1936, and carried on for one year. The fiscal year was divided for study purposes into 2 periods of 6 months each, the reason for which will become apparent later.

During the first 6 months, convalescent serum and antitoxin were given to alternate patients who on admission appeared to have exhibited scarlet fever of a moderately severe grade. The determination of the severity of the case and the necessity for serum was the responsibility of two resident physicians (chief and senior) who have been on the Communicable Disease Service for over 10 years. They had no part in the choice of serum to be used. Whenever the serum sensitivity test was positive when antitoxin was to be administered, convalescent serum was given instead, and the case was excluded from the series. The next patient needing serum was given antitoxin if the sensitivity test was negative. Serum was administered in the admitting room prior to removal of the patient to the scarlet fever pavilion.

The scarlet fever convalescent serum used was obtained from recently recovered donors bled in the Department

* Read at a Joint Session of the Health Officers, Laboratory, and Epidemiology Sections of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 28, 1938. (This study was aided by WPA Project No. 82-4-120).

of Health Serum Clinic, and each batch of serum represented the contribution of about 10 donors. Thirty-three samples of serum from as many batches were tested for antitoxin content by the Veldee rabbit ear method, and no batch contained more than 2 units per cc. The dose was 30 cc., and a patient received no more than 60 units of antitoxin when convalescent serum was administered. The scarlet fever antitoxin used was obtained from the Laboratories of the Michigan State Department of Health, and each therapeutic dose (10 cc.) contained a minimum of 6,000 units. The ratio, then, of antitoxin in scarlet fever antitoxin to that in scarlet fever convalescent serum was roughly of the order of 100:1.

The data obtained during the 6 month period were the result of treating alternate cases of moderately severe scarlet fever with convalescent serum and antitoxin. The method of serum assignment was expected to result in comparable groups. To try this assumption, the serum groups were tested with respect to the following important characteristics: distribution of cases by month, by age, by temperature on admission to hospital, by day of disease treatment was begun, and finally by the proportion of cases with significant associated conditions. The two serum groups did not differ with respect to the characteristics considered, and for our purpose may be looked upon as comparable in all respects except kind of serum administered.

RESULTS OF TREATMENT FOR THE
6 MONTH PERIOD, AUGUST 1, 1936,
THROUGH JANUARY 31, 1937

During the first 6 months of the study 346 patients with moderately severe scarlet fever were admitted to the Communicable Disease Service. A few patients who belied their real condition upon admission to hospital were

originally in the series but obviously did not belong there because they were of the toxic or septic type necessitating different treatment. The elimination of such cases accounts for the slight discrepancy in the serum group totals. One dose of convalescent serum was given intramuscularly to 177 patients while 169 received one dose of scarlet fever antitoxin by the same route.

Augmented Treatment—Whenever a patient showed no improvement in clinical condition, or the admission temperature had been maintained or risen during a 24 hour period following serum treatment, an additional dose of serum was administered. When this was found necessary, it was charged as a failure against the serum originally administered. Cases with such augmented treatment were excluded from the study in order that the value of one dose of either serum might be determined. In Table I the number of cases in which augmented treatment was necessary is shown for both convalescent serum and antitoxin. Additional serum was administered in 14 cases in which convalescent serum was initially used, compared to 11 patients among the group given antitoxin. One case subtracted from the convalescent group and added to the antitoxin group would change the proportion but slightly, and when tested statistically no significant difference is demonstrated.

TABLE I
Serum Treatment of Scarlet Fever
Number and Proportion of Cases with
Augmented Treatment by Type
of Serum Used

<i>Serum</i>	<i>Total Cases</i>	<i>Augmented Treatment</i>	<i>Per cent Aug. Treatment</i>
Convalescent	177	14	7.9
Antitoxin	169	11	6.5

Temperature Pattern — Cases were classified into 3 groups in relation to the effect of serum on temperature. The first group includes cases in which

the temperature declined to normal or to within 1 degree of normal within 24 hours of serum administration, the temperature remaining normal thereafter for a minimum of 5 days. The second group contains cases in which temperatures declined by lysis within 5 days, a reaction considered average for moderate cases of scarlet fever treated without serum. The third group consisted of patients whose fever continued for a period longer than 5 days. When the two sera are compared on the basis of this classification, no noteworthy difference is demonstrated (Table II).

TABLE II

Serum Treatment of Scarlet Fever

Temperature Pattern of Cases by Type of Serum Used

Temperature Pattern	Number of Cases		Per cent of Total Cases	
	C	A	C	A
Normal	88	88	54.0	55.7
Lysis (5 days)	46	40	28.2	25.3
Con't fever	29	30	17.8	19.0
Totals	163	158	100.0	100.0

Uncomplicated Cases—Scarlet fever is a disease in which complications are quite prevalent, and in general it may be stated that slightly over one-half of the hospital cases of a moderately severe grade will develop complications

of one sort or another. In Table III, the number and proportion of uncomplicated cases are shown by type of serum used. A comparison of the two sera with respect to this factor shows little difference.

TABLE III

Serum Treatment of Scarlet Fever

Uncomplicated Cases by Type of Serum Used

Serum	Total Cases	Uncomplicated Cases	Per cent Uncomplicated
Convalescent	163	70	43.0
Antitoxin	158	68	43.7

Occurrence of Complications—Certain complications occur with greater frequency in scarlet fever than others. The commonest in hospital practice are rhinitis, cervical adenitis, and suppurative otitis media, in the order named. In Table IV the complications noted during the first 6 month period are listed with respect to frequency, proportion, and the type of serum used. Rhinitis and cervical adenitis occurred with the same frequency. The incidence of suppurative otitis media as well as the remainder of the complications shown in the table occurred too infrequently to warrant analysis.

Proportion of Cases with Multiple Complications—The complication analysis was carried one step further by determining the number of complica-

tions an individual contracted with relation to the type of serum used. Here again, the differences are not striking (Table V). The frequency and proportion of cases in which one, two, or three complications occurred are practically the same. When only complicated cases are considered, each case has less than two complications, whereas the inclusion of all cases in each serum group shows less than one complication per case.

late release, if the therapeutic effect of serum lasts for an average period of 2 weeks. In Table VI the dismissal status of cases admitted to hospital during the first 6 months is shown by age, number, and proportion of late dismissals, and by type of serum used. An analysis of the table shows that in the antitoxin group a larger proportion of patients aged 1 to 4 and 5 to 9 were detained than in the convalescent serum group. The two age groups in

TABLE VI
Serum Treatment of Scarlet Fever

20+	20	17	2	4	10.0	23.5
Totals	160	158	43	56	26.9	35.4

Dismissal Status—Besides the serious complications which might hinder the dismissal of a patient at the end of 14 or 21 days of isolation, such minor conditions as excoriations about the nose and mouth, paronychia, positive cultures from nose, throat, or ear from pre-admission institutional cases were also included as causes for late dismissal. Both convalescent serum and antitoxin in the dosages given could not reasonably be expected to exert much influence on such causes for

question contain the largest number of cases. In the 10 to 14 age group, which is smaller, the reverse is true. The difference would appear to be considerable, but upon testing the data statistically, no significant difference is noted ($p = .38$).

COMMENT

When the therapeutic results of the first 6 months of the study are compared, there appears to be no significant difference between convalescent

serum and antitoxin in the treatment of moderately severe scarlet fever. This type of scarlet fever is one for which serum therapy has always been used at Herman Kiefer Hospital. A control group not treated with serum was not included in the series for this reason. Therefore, from this study, one cannot determine whether without serum there might have been equally good results. Furthermore, the possibility of a nonspecific serum effect was not ascertained. In order to answer these questions a third serum was introduced, on February 1, 1937, and this was used until the experiment terminated on July 31, 1937. The new serum was nonspecific for scarlet fever and contained 1,000 units of diphtheria antitoxin per therapeutic dose of 10 cc. This was furnished by the Laboratories of the State Department of Health and was from horses which had not been used previously in the production of antistreptococcic sera. The nature of the serum was unknown to the hospital medical personnel until after the termination of the study, so that in so far as is humanly possible, no bias was introduced. The 3 sera were given alternately to moderately severe scarlet fever patients as they were admitted to the Communicable Disease Service. Needless to say, the antitoxin and the convalescent serum used during this period were not measurably different from those used during the first 6 months. In the analysis which follows, "special" serum refers to the newly introduced nonspecific serum. When specific serum is mentioned, convalescent serum, antitoxin, or both, are meant.

The data collected during the second 6 months were put to test with respect to comparability of serum groups in a manner similar to that accorded the data of the first 6 months. The 3 serum groups were found to be comparable with respect to the charac-

teristics tested except kind of serum administered.

RESULTS OF TREATMENT FOR THE
6 MONTHS, FEBRUARY 1, 1937,
TO AUGUST 1, 1937

During the last 6 months of the study, 773 patients with a moderately severe type of scarlet fever were dismissed from the Communicable Disease Service. The number of cases was distributed among the 3 serum groups as follows: special serum, 252; convalescent serum, 261; antitoxin, 260. The slight discrepancy in group totals is due, as before, to elimination from each group of toxic and septic cases inadvertently classified as moderately severe on admission.

Augmented Treatment—The number of cases in each group needing additional serum following administration of the initial dose was determined (Table VII). Only 12 and 13 cases receiving convalescent serum and antitoxin respectively needed additional serum; the proportion of such cases is the same. In contrast, the special serum group shows augmented treatment administered to 74, a proportion of 29.4 per cent. When this proportion is compared with that for both convalescent serum and antitoxin, the ratio is nearly 6 to 1. Thus a marked difference is noted in the number of failures as between nonspecific and specific serum therapy. As for the earlier period, failures were eliminated from each group for the remainder of the analysis.

TABLE VII
Serum Treatment of Scarlet Fever

*Number and Proportion of Cases with
Augmented Treatment by Type
of Serum Used*

Serum	Total Cases	Augmented Treatment	Per cent Aug. Treatment
Special	252	74	29.4
Convalescent	261	12	4.6
Antitoxin	260	13	5.0

TABLE VIII
Serum Treatment of Scarlet Fever
Temperature Pattern of Cases by Type of Serum Used

Temperature Pattern	Number of Cases			Per cent of Total Cases		
	S	C	A	S	C	A
Normal	79	171	160	44.4	68.7	64.8
Lysis (5 days)	69	46	52	38.8	18.5	21.1
Continued fever	30	32	35	16.9	12.8	14.2
Totals	178	249	247	100.1	100.0	100.1

Temperature Pattern—This factor shows but little variation when the result of specific treatment is compared (Table VIII). There is, however, a striking decrease in the proportion of cases in which the temperature reached normal within 24 hours in the special serum group. The proportion of cases in which the temperature declined by lysis is higher than noted in the specific groups. The proportion of cases with continued fever was slightly greater in the nonspecific serum group.

Uncomplicated Cases—The number of uncomplicated cases in the group receiving special antitoxin was 66 (Table IX). There were 119 uncomplicated cases in each of the convalescent serum and antitoxin groups. The proportions for the various groups were respectively 37.1, 47.8, and 48.2.

It is readily apparent that no difference appears in the proportion of uncomplicated cases in the convalescent and antitoxin groups. The special group again suffers by comparison, and the difference is almost significant ($p = .03$).

TABLE IX
Serum Treatment of Scarlet Fever
Uncomplicated Cases by Type of Serum Used

Serum	Total Cases	Uncomplicated Cases	Per cent Uncomplicated
Special	178	66	37.1
Convalescent	249	119	47.8
Antitoxin	247	119	48.2

Occurrence of Complications—The complications are listed in Table X. When the incidence of the 3 common complications of scarlet fever is compared with respect to the three sera tested, one notes as striking a similarity

TABLE X

Scarlet fever, recurrent	1	0.4
Total cases treated	178		249		247	

TABLE XI

Serum Treatment of Scarlet Fever

Number of Complications per Case by Kind of Serum Used

Kind of Serum		Number of Complications per Case				Complications Group			Entire Group	
		1	2	3	4	No. of Cases	No. Compl.	Compl. per Case	No. of Cases	Compl. per Case
S	No.	59	42	8	3	112	179	1.6	178	1.0
	Per cent	52.6	37.5	7.2	2.7					
C	No.	85	33	10	2	130	189	1.5	249	0.76
	Per cent	65.4	25.4	7.7	1.5					
A	No.	88	31	6	3	128	180	1.4	247	0.72
	Per cent	68.7	24.2	4.7	2.3					

in the incidence rates of these complications for the convalescent and antitoxin-treated groups as was encountered during the first 6 months. Cases receiving special serum show a moderately higher rate for cervical adenitis and rhinitis, and a proportion twice as high for suppurative otitis media. The incidence of the remaining complications listed in the table is too small to warrant consideration.

Proportion of Cases with Multiple Complications—The number of complications per person in the specific serum groups show little variation (Table XI). A smaller proportion of cases receiving nonspecific serum developed but one complication. However, the proportion of cases having two complications was greater for this group. Taken in the aggregate, there is little difference between the serum groups with respect to the number of complications per complicated case.

When all cases in the respective groups are used as the basis for comparison, then the special group shows an average of one complication per case while the specific serum groups show less than one.

Dismissal Status—The remarks previously made with respect to the questionable value of serum on the dismissal status applies equally well to an analysis of the last 6 months' experience. The results previously noted are borne out in Table XII, for although the proportion of late dismissals is higher in the group which received special serum, yet the difference between this group and those receiving specific serum is of slight consequence. The difference between the convalescent serum group and the antitoxin group is practically nil. It will be recalled that on cursory analysis of the first 6 months' experience there appeared to be a real difference in the

TABLE XII

Serum Treatment of Scarlet Fever

Dismissal Status of Cases Admitted to Hospital

Age	Total in Group			Late Dismissals			Proportion of Late Dismissals		
	S	C	A	S	C	A	S	C	A

1-4 "	30	56	57	20	24	25	51.3	42.9	43.9
5-9 "	82	96	116	17	17	19	20.7	17.7	16.4
10-14 "	36	58	48	5	6	4	13.9	10.3	6.2
15-19 "	8	11	6	..	1	3	50.0
20+	13	27	20	3	3	2	23.1	9.1	10.0
Totals	178	249	247	45	52	53	25.3	20.9	21.5

proportion of late dismissals between the convalescent serum group and the antitoxin group, but this was not borne out by test. Thus, the second 6 months' experience is in keeping with that of the first 6 months.

COMMENT

During the last half of the study, 3 sera were used; 1 was nonspecific, and 2 were specific. For all factors tested, specific sera showed better results than did the nonspecific serum. Furthermore, the results obtained with specific serum bear out the experience noted during the first 6 months, namely, that no real difference was demonstrated with respect to their therapeutic value under the conditions of the study. It would appear then that on the basis of the year's study, convalescent serum and scarlet fever antitoxin proved equally effective in the treatment of moderately severe scarlet fever.

It is interesting to conjecture the reason for the similarity in therapeutic effect exhibited by convalescent serum and antitoxin in the doses administered. Several possibilities come to mind. Because this experience covers a single epidemic cycle, one might object that the test period is too short, and that for this reason no real benefit has been demonstrated. The test period might well be extended, but the objection would appear to be less pertinent when the therapeutic result obtained with nonspecific serum is contrasted with that obtained when specific sera were used. The differences in some instances are striking and all are in the same direction, namely, in favor of specific sera. This reason does not appear to be tenable.

A second possibility is the presence in both sera of an antibody other than an antitoxin or an antibacterial substance to which their similar therapeutic effect might be attributed. This is not likely.

A third possibility is that scarlet fever is at present rather mild in Detroit as it is generally in the United States, and that use of either convalescent serum or antitoxin in the dosage used is sufficient to give satisfactory results. This might be interpreted in one of two ways: First, the antitoxin content of both sera is solely responsible for the therapeutic effect obtained. A few workers, particularly Rhoads and Gasul,¹ have implied, if not definitely stated, that the therapeutic value of any scarlet fever serum was entirely dependent upon its antitoxin content. It does not seem plausible that two sera, the ratio of whose antitoxin content is of the order of 100 to 1, should show the same therapeutic results when tested under control conditions. It must be borne in mind that the cases treated in this study were all of the moderately severe type of scarlet fever; all had temperatures ranging between 102° and 105° upon admission to hospital, and all other factors tested were similar. It seems unlikely that the antitoxin content alone determined for both sera the therapeutic results obtained. If this were the case, it would be equivalent to stating that equally good results would be obtained if a therapeutic dose of antitoxin consisting of not more than 60 units were used instead of one containing 6,000 units, the dosage used in this study. This does not appear to be very likely. Second, the therapeutic result demonstrated by antitoxin is due to its high antitoxin content, and a similar result in the case of convalescent serum is due to the presence of antibacterial substances, augmented slightly perhaps by the small amount of antitoxin to be found in this type of serum. This seems the most likely explanation.

SUMMARY AND CONCLUSIONS

The therapeutic effect of scarlet fever convalescent serum, scarlet fever anti-

toxin, and a nonspecific serum was studied during one year beginning August 1, 1936, and ending July 31, 1937. During this time, 995 moderately severe scarlet fever patients were admitted to hospital, and there received a single dose of one of the sera by the intramuscular route. The study was controlled by alternation in administration of sera. No statistical difference was demonstrated between the serum groups when certain status-on-admission factors were tested. From the therapeutic results obtained in this study, the following conclusions are drawn:

1. Convalescent serum and antitoxin in the dosage given and route utilized appear to

exert a similar therapeutic effect with respect to the factors studied.

2. The value a scarlatinal serum exhibits in the treatment of moderately severe scarlet fever does not appear to be gauged entirely by its antitoxin content.

3. If there is value in using nonspecific serum in the treatment of moderately severe scarlet fever, then there is greater value in using specific serum, namely, convalescent scarlet fever serum or scarlet fever antitoxin.

NOTE: The authors wish to express their appreciation to Dr. C. C. Young and Dr. W. A. Bunney for their assistance in the preparation of the scarlet fever antitoxin and the diphtheria antitoxin used in this study.

Forerunners of Modern Preventive Medicine

THE foundations of the administrative practice of modern preventive medicine are to be seen in the work of the practitioners of medicine in the eighteenth century. The work of Mead has been instanced in this connection, and he was the forerunner of others.

Heberden and Huxham studied fevers; Fothergill described malignant sore throat; Smellie and William Hunter practised and advanced the art of obstetrics; and Charles White applied antiseptic principles to it; Haygarth of Chester introduced notification and isolation of infectious disease; Richard Bradley studied plague at Marseilles; Sir John Pringle began hygienic reform in the British Army; Lind laid

down principles for the abolition of scurvy among seamen and the prevention of typhus fever; Sir George Baker wrote on the cause of Devonshire colic and palsy; Sir Gilbert Blane studied the diseases of the Navy; Percival denounced the lack of hygiene in crowded factory towns and initiated "industrial welfare"; and Edward Jenner introduced vaccination for smallpox in place of the inoculation method practised for seventy years before.

Thus, much research work had been and was being done in fields where the safety of the community and the interest of the practitioner coincided. Walter Elliot, Minister of Health, Health and The State, *Brit.M.J.* Feb. 25, 1939.

Social Security Needs for Vital Statistics Records*

WILLARD C. SMITH, F.A.P.H.A., AND
I. S. FALK, PH.D., F.A.P.H.A.

Bureau of Old-Age Insurance; and Bureau of Research and Statistics, Social Security Board, Washington, D. C.

THE administration of the social security program involves the collection of a large volume of vital and economic data pertaining to persons covered by the old-age insurance, the unemployment compensation, and the old-age assistance provisions of the Social Security Act. The present discussion is concerned particularly with the significance and relationship of vital statistics records to the data arising out of the administrative operations of the Bureau of Old-Age Insurance.

It was originally estimated that there would be approximately 26 million persons whose wages would be taxable under Title VIII of the Act. As a matter of fact there are now more than 41 million persons with account numbers, with about 32 million persons already accumulating wage credits.

STATISTICAL ITEMS IN INSURANCE CLAIM RECORDS

The applications for account numbers furnish certain essential data regarding the applicant, including his name, residence, age at last birthday, date of birth (subject to later verifica-

tion), place of birth, sex, color, date of first employment in a taxable occupation after November 24, 1936, father's name and mother's maiden name.

Since the amount of the old-age benefit is determined on the basis of the taxable wages earned since January 1, 1937, an informational report based on the employer's tax return is required. This provides additional economic information, including the period of employment, the employer's name and account number, the total taxable wages earned by the employee, and the state in which such wages were paid. For each registered employee there has been established a wage ledger sheet with a record of wages earned during each half of the year 1937. These wages can be tabulated for each half of that year and for each quarter of the year 1938 and (if quarterly reporting continues) thereafter. Under the present provisions of the Social Security Act, monthly benefits will not become payable until January 1, 1942.

During the first 5 years of the old-age insurance program, lump sum settlements of claims are payable for each covered wage earner who dies or who attains age 65. To date there have been 213,137 claims filed, of which 117,852 were death and 95,285 were

* Read before the Vital Statistics Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 25, 1938.

age-65 attainment cases. The amount payable in each case is $3\frac{1}{2}$ per cent of the total taxable wages earned by the employee since January 1, 1937. The number of claims will increase as time goes on, the ultimate limit being the actual number of deaths plus the age-65 attainments among covered wage earners.

In the development and adjudication of these claims many items of statistical information are obtained, some of which have not hitherto been available from so satisfactory a source, for so large a number of persons, or with so high a degree of accuracy. This body of information includes the following:

A. All Claims

1. Employee's account number
2. Type of claim (life or age-65 attainment)
3. Origin of claim (state and field office)
4. Domicile of wage earner at time of filing application or at time of death
5. Sex
6. Color or race
7. Occupation
8. Total wages upon which amount of claim is based
9. Amount of claim
10. Place of birth
11. Date of birth
12. Number of different employers (since January 1, 1937)

B. Death Claims

1. Age at death
2. Place of death
3. Date of death
4. Marital status of wage earner at time of claim
5. Age of spouse
6. Number of children, by age
7. Number and relationship of payees to wage earner
8. Amount of expenses in last illness
9. Amount of funeral expenses

C. Age-65 Attainments

1. Type of evidence required to establish date of birth on life claims
2. Date of attainment of age 65

Both life and death claims are of interest from the standpoint of vital statistics.

The characteristics of our 41 million potential claimants have been de-

termined from a 10 per cent sample. This population is, of course, dynamic. Additions to this registered population are being made constantly as young persons enter the labor market and as workers formerly in non-covered occupations shift to covered employments. Subtractions from the registered population occur from two causes only, death and attainment of age 65. It must be pointed out that the shifting of an employee from covered to non-covered employment does not change his status as a potential claimant nor subtract him from the total registered population. Such an employee may, at any later time prior to death or attainment of age 65, return to covered employment and subsequently qualify as a claimant.

In estimating the expected subtractions from our registered population use must be made of the mortality statistics and of the life tables of the U. S. Bureau of the Census. Thus the Social Security program has, and will continue to have, pressing need of vital statistics records.

May we depart for a moment from consideration of the record forms and the statistical data involved in the administration of the system which is now in operation. You will be interested in some contemplated changes in the present system which are being actively explored and which, if adopted, would have substantial implications for statistical problems of coming years. As many of you know, the President has suggested to the Social Security Board that it examine the possibility of liberalizing the old-age insurance benefits. He has specifically raised questions concerning the possibility of providing benefits not only for those insured workers who attain old age, but also for aged wives and widows and for young children of persons dying before reaching retirement age. The Social Security Board is studying the possi-

bility of such liberalization of the old-age insurance benefits, and in addition, is exploring the possibility of providing benefits for workers who become permanently and totally disabled before attaining retirement age.

It is, of course, too soon to say what the results of these studies will be. We would at this time only call to your attention that if any or all of these contemplated new benefits should become part of the social insurance system, the vital statistics needs will be considerably expanded. For example, records concerning marital status and family relationships will become important. Many types of claims will involve statistical records concerning the relationship of parent to child, and there will be need to know the age of a child who might be eligible to dependent children's benefits. Accordingly, the administration of the system may become as actively concerned with birth records as with death records—birth records being important in establishing not only parent-child relationship, but also the age of a child. It may, therefore, become desirable or necessary not only that the death certificate should carry an account number, but also that the birth certificate should carry the account number of either parent or of both parents. Obviously the problems involved in making birth certificates useful for Social Security purposes are closely related to problems we now are facing in respect to death certificates.

THE RÔLE OF BIRTH CERTIFICATES IN OLD-AGE INSURANCE ADMINISTRATION

For administrative reasons, it is necessary in the case of life claims to establish the exact age of the wage earner, and in the case of death claims to establish the fact and date of death. Owing to the comparatively recent development of birth registration in the United States, most persons who be-

come 65 years of age during the period 1937-1942 will be unable to obtain birth certificates. Moreover, since the claims are for small amounts during the early years of the old-age insurance program, the Social Security Board has been disinclined to impose any expense upon the claimants, either for certified copies of birth or death certificates, for notary fees, or for other purposes.

However, as the program progresses, and especially when monthly benefits become payable, it will be necessary to simplify the procedure for establishing proof of age. The ideal proof of age is a birth certificate filed under the regularly established birth registration machinery. As time goes on, more and more of the wage earners will be able to obtain such certificates filed at the time of birth, or within the period for delayed registrations permitted by the respective state registration laws.

The problem of delayed registration has been given special consideration during recent years, formerly by a committee of the Vital Statistics Section under the chairmanship of Dr. Stewart Thompson, and now by a committee of the American Association of State Registration Executives, under the chairmanship of Dr. Martin B. Woodward. The Social Security Board will follow with interest the work of this committee. It is recognized that any legislation permitting registration of births long after their occurrence must be carefully safeguarded against fraud and inaccuracy. Nevertheless, if some solution satisfactory to the state registrars could be devised for this problem, we would be able to rely upon the birth certificate as a suitable proof of age. Lacking such a solution, and until the time when all wage earners will have been born subsequent to the establishment of effective birth registration, we must rely upon other methods of proving age. In the meantime, every appropriate effort should be made

to strengthen the existing system of birth registration.

But proof of age is not the only purpose which can be served by the birth certificate. If dependent children's benefits were provided, proof of relationship would be also served. In addition, information on the social and economic status of our covered wage earners would be helpful in administration and in providing the statistical basis for revisions in the Act which may have to be made from time to time.

As a background for these and other studies it is necessary to give special attention to the standardization of statistical classifications as to special items of information. Let us digress at this point from consideration of birth certificates to illustrate the problem. Among the items which require special classification codes, we might mention occupation and industry. Several attempts have been made to harmonize the occupational classifications now being used by different branches of the federal government, such as the Bureau of the Census, the Works Progress Administration, the Bureau of Labor Statistics, and the Social Security Board.

The Social Security Board is co-operating with the Central Statistical Board and the American Statistical Association in developing an occupational code which can yield comparable results when applied to occupational information obtained from employers, from birth and death certificates, from U. S. Employment Service records, or from population census schedules. The occupation of each old-age insurance claimant is furnished on the employers' report form, and tests have established that this is a satisfactory source of such information. It is hoped to ascertain from the same source the occupation of nearly all holders of Social Security Account Numbers. The availability of occupational data concerning so many wage earners from such a reliable

source is most reassuring to statisticians interested in the study of occupational variations in mortality and in studies of births by social and economic status of the parents. This new opportunity to develop useful statistics by relating the existing birth and death information to the wage records and claims data of the Social Security Board justifies us in looking forward to the development in the United States of a new basis for fruitful study of mortality, fertility, and other population problems.

THE RÔLE OF DEATH CERTIFICATES IN OLD-AGE INSURANCE ADMINISTRATION

The death certificate has an even greater significance to old-age insurance administration. As noted, it is necessary during these first 5 years to have prompt notification, with proof, of the fact and date of death. A certified copy of the death certificate would be desirable for both administrative and statistical purposes but for the fact that we must have proof of death before the monthly reports of the local registrars will have reached the state registrars. Even in these early years of the old-age insurance program, when claims are for relatively small amounts, 56 per cent of the applications are filed within 45 days. Nearly half of these, or 25 per cent of the total, are filed within 15 days. Promptness of reporting may be expected to be even more striking as the size of claim increases. Unless we devise some method of obtaining notification and proof within less than 10 days after the fact of death, our field agents will frequently be obliged to obtain information direct from local registrars.

In order to avoid both the annoyance of these officials and the numerous searches in their confidential files which would be necessary, it is proposed to have a special death certificate printed by the Social Security

Board and distributed to the local registrars through the existing registration machinery. This certificate would be filled out at the time of issuing the burial permit and mailed direct to the Bureau of Old-Age Insurance.

This special certificate will not carry all the items required on the Standard Certificate of Death. It will not include, for example, any of the items which relate to cause of death. Such information can be more reliably obtained for statistical purposes from the Division of Vital Statistics in the Bureau of the Census, where the cause is coded according to the *International List of Causes of Death*, complete data being obtained if necessary by querying directly to the attending physician.

This special certificate will, however, include the name, sex, race, age at death, place and date of death, and such other identifying personal particulars as are necessary or helpful to the development and adjudication of old-age insurance claims. After monthly benefits become payable in 1942 (or before then if the Act is amended), such a certificate will enable the board to determine promptly when payments should cease or when they should be made payable to beneficiaries covered by the Social Security Act instead of to the deceased wage earners. Without some very prompt means of ascertaining the fact of death much trouble and expense may be involved in recoveries from their estates of overpayments or incorrect payments to beneficiaries.

The procedure proposed for obtaining the special death certificates is to have them printed by the Social Security Board, bound in pads, and distributed to the local registrars through the state registrars' offices, along with the regular supplies of state certificate blanks. The Social Security certificates will be in duplicate, printed on colored paper. The local registrar will execute

the forms in duplicate at the time of issuing the burial permit, being asked to take special pains to insure that the Social Security Account Number is copied correctly. The original of the special certificate will be mailed at once to the Social Security Board in an official return envelope, a supply of which will have been received with the blank forms. The duplicate will be attached to the original state certificate and forwarded to the state registrar with the routine monthly report required by local regulations.

In the state office, the duplicate copy of the Social Security Board certificate will be checked and forwarded to the U. S. Bureau of the Census with the regular shipment of transcripts. In the processing of the transcripts in the Bureau of the Census, the cause-of-death code will be entered on the Social Security Board duplicate and forwarded to the Bureau of Old-Age Insurance. Thus, the original copy having been mailed direct by the local registrar, will accomplish the purpose of establishing, for Old-Age Insurance purposes, prompt notification of the fact and date of death; and the duplicate copy, arriving some weeks later, will bring to us from the Division of Vital Statistics of the Bureau, the cause-of-death code which will then be punched on our claims cards.

This suggested plan and procedure has been discussed with Dr. Dunn and Dr. Collinson of the Bureau, who have generously collaborated in the development of the procedures, with members of the Vital Statistics Section Council, and with several of the state registrars with whom there has been opportunity for conference. The proposal is placed before you today for consideration and with the hope that your discussion will help us to develop a procedure which will be acceptable to all concerned. Needless to say, it is expected that the Social Security Board will arrange mutually satisfactory com-

pensation both to state and local registrars.

Other points on which we invite your comments at the session today are the

inclusion of the Social Security Account Number on the death certificate and the Account Numbers of the parents on the birth certificate.

DISCUSSION

THOMAS W. CHAMBERLAIN

State Board of Health, Jefferson City, Mo.

MR. Smith has very ably presented the needs of the Social Security Old-Age Insurance Division. The proposed plan for furnishing blanks in duplicate to the registrar seems to be a practical and simple solution of the problem of securing proof of death promptly. Mr. Smith's hint of compensation to the local registrar is very interesting and I trust that we will receive further information. Some additional form of remuneration to the local registrar should reduce his complaints of overwork with underpayment to a minimum and generally make the job of local registrar more interesting.

However, this is not the whole problem; Mr. Smith has suggested a much greater one. It is evident from his remarks that we have experienced only the beginning of the demand that will eventually be made for our services. It may discourage some of us to learn of the probability of increased demands in the future when those of the present are so difficult. In meeting the demands of the present the states have met the problem in various ways, some of which are: the training and supervising of one or more clerks from the state Social Security office: the requirement that all inquiries originate in the local registrar's office and, in one instance, the neglect of regular and necessary duties in the vital statistics bureau. In striving to meet these de-

mands we have acknowledged that one of the most important duties in vital statistics is being of service to our people. It follows then that we must develop with the social legislation of today in order that we may continue to be of service.

A nation-wide social security program calls for a nation-wide system of vital statistics. The adoption of the new certificate forms will not be sufficient. We must standardize our methods as well as our forms. We must replace our present laws with a new model law. We must establish minimum standards for delayed certificates, for corrections or amendments, for adopted children's certificates, and for other procedures. We must persuade our health officers of the need for increased personnel and equipment in anticipation of what lies before us.

We are all proud of the voluntary relationship between the states and the U. S. Bureau of the Census. It is within our power to better our record and make an even greater contribution to the health and welfare of our own people and those of other states by a voluntary agreement on methods in vital statistics.

All this has been said many times in the past by those much better qualified than I, but it can be done, and it should be done, now. If we postpone action there is a possibility that we

may compel social agencies to organize their own machinery for the collection of vital statistics data independently of ours. It is only fair to point out, however, that no such attempt has been initiated by the Old-Age In-

surance division of the Social Security Board.

As a newcomer in vital statistics, it seems very much in order that we hear from some of the more mature and experienced vital statisticians present.

Public Health

PUBLIC health is a comprehensive science. Many contribute to it—the engineer, the architect, the lawyer, the administrator, the sociologist, the chemist, the physicist, the physiologist, the biologist, the biochemist, and so forth. But the chief contributor is naturally the exponent of medicine. The doctor was at first faced with the problem of treating a disease, a departure from the normal. In order to recognize the disease he had to know

the condition and state of the healthy body. Hence the importance of anatomy and physiology in the medical curriculum. Next he was occupied in studying the causes of disease: *Felix qui potuit rerum cognoscere causas*. Thence it was a short step to study how these causes might be prevented from assailing the human healthy body—in other words, preventive medicine. Walter Elliot, Minister of Health, Health and the State. *Brit.M.J.* Feb. 26, 1939.

Potentialities of Public Health Engineering in Relation to the Social Security Act*

ROY J. MORTON, F.A.P.H.A.

*Assistant Professor of Preventive Medicine and Public Health,
Vanderbilt University School of Medicine, Nashville, Tenn.*

PUBLIC health work under the Social Security Act is essentially a new program. The Act was passed in 1935 and funds became available about 2½ years ago. It is, therefore, too early to estimate its actual value on the basis of experience. This legislation and the regulations under which it is administered obviously contemplate a long-range program, and one of increasing influence. Remarkable progress has already been attained. The most significant accomplishment of this program has been the formulation and wide acceptance of fundamental administrative policies which should serve as the foundation for greater achievements.

A discussion of the encouraging possibilities afforded by a new program is attended by certain dangers two of which may be mentioned. Undue optimism, incited by favorable reports may lead to overdevelopment of the immediate expectations of those concerned. An enthusiasm which is based on "wishful thinking" rather than careful analysis may not be sustained by later experience and ultimately may

contribute to a decline in morale when inspiration for continued effort is needed. On the other hand, there is danger that a discussion of potentialities may be too realistic and confined only to immediate and superficial values. The men who have developed this program, while practical, have been idealistic in the truest sense, dealing in fundamental principles and visualizing the developments of the future. The administrative policies of the program are not limited by present practice. They can, and undoubtedly will, be readjusted so as to utilize advances in knowledge and improvements in procedure.

The writer has no inclination to "overstate the case" of public health engineering in relation to the Social Security Act or to arouse an unwarranted degree of optimism. The total annual appropriation to the U. S. Public Health Service for all purposes in this program is relatively small—about 8 cents per capita. Obviously the immediate development of adequate public health engineering facilities to serve all areas in the country cannot be expected. The outlook of public health engineering in the Social Security Program is indicated by encouragement of the scientific approach to public health problems

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 26, 1938.

through professional education and research; and by the recognition of environmental sanitation as an essential part of public health programs—federal, state, and local. In this paper I wish to emphasize some unparalleled opportunities afforded by this program to extend and improve our methods in public health engineering and to develop environmental hygiene in its broader aspects.

FUNDAMENTAL ASPECTS

There is need for a more unified point of view concerning the rôle of the engineer in public health work. Public health engineering is a recent development and it has not yet outgrown the fact that it had its origin in two different fields of activity; namely, sanitary engineering and sanitary inspection. From the standpoint of time and service rendered neither of these was primarily public health. Sanitary engineering is concerned especially with design, construction, and operation. Although important benefits to public health are provided by sanitary engineering, a sanitary engineer, engaged in the design and construction of a water works system, a sewage treatment plant, or a garbage incinerator, devotes more attention to materials of construction, hydraulics and heat losses than to morbidity rates, sources and modes of infection and physiological responses of human beings to their environment.

Sanitary inspection was the forerunner of municipal and rural public health engineering. This activity was intended to reduce environmental health hazards but it has been, and frequently is, unscientific as a public health procedure. For example, a recent survey of the sanitation program in a city with an excellent health department shows that, exclusive of milk and food control, 34 per cent of the accomplishments recorded as sanitation were abatements

of nuisances pertaining to refuse, garbage, and trash. Many of the earlier programs of sanitary inspection consisted almost entirely of routine law enforcement and the abatement of minor nuisances which had no direct relation to public health.

Public health engineering is more comprehensive and, in reality, includes the public health aspects of both sanitary inspection and sanitary engineering. The dominant characteristic of public health engineering is that its chief concern is with public health activities. The prestige and potentialities of public health engineering as a professional entity are based upon the close relation of environment to human health, and upon the further fact that adjustment of the environment involves the application of engineering principles. This axiomatic and oft-repeated basis of this field was well described by Holmquist and Dappert about a year ago in a discussion of the "Expanding Scope of Engineering in State Health Departments."¹ They stated:

Public health work deals with the application of science to the problems of man's relation to his environment. The task of the public health engineer is to assure necessary favorable conditions and to prevent or minimize the unfavorable. The air we breathe, the water we drink, the food we eat, the light by which we see, the people with whom we come in contact—in fact, any of the conditions of competitive life under which we live—are all a part of our environment. And just as long and broad as you can conceive environment to be, just that long and broad is the field of public health.

Public health engineering is a composite specialty of the engineering profession. It is related to, but does not embrace, many other phases of engineering; it does embrace a number of functions which have not been generally recognized as engineering. It is based upon the same fundamental sciences as other branches of engineering—chemistry, biology, mathematics, mechanics,

and physics. The essential difference is that while its basis is engineering, its primary objectives, and therefore its principal criteria of efficiency and economy, are valued in terms of human health. For example, a sanitary engineer may construct a water purification plant which is a marvel of engineering efficiency and economy. But unless it increases the degree of protection against ill-health or tends to promote better health among people it is a failure as a public health engineering project. On the other hand, a worker who uses his knowledge of engineering effectively in a program of education against environmental health hazards renders a valuable service. Many activities such as rural sanitation, school sanitation, or the routine inspection of food and milk supplies, may appear commonplace and non-technical. However, a background of technical knowledge and an engineering point of view are necessary for the solution of such environmental problems. Moreover, this provides community-wide protection of value just as in the supervision of the larger sanitary engineering utilities, as public water supplies and sewage disposal systems.

Probably much of the confusion and duplication of effort in environmental sanitation activities are caused by failure to comprehend fully and accept the expanded rôle of engineering in public health work. Engineering schools have been disregarding of this development; some health officers fail to appreciate it; and the perspective of many engineers now engaged in public health work is too restricted by traditional concepts of what engineering does or does not include.

ESSENTIAL BASES OF ADVANCEMENT

The Social Security Act demands the establishment and maintenance of "adequate public health services." This is a challenge which necessitates

continued study and analysis of the fundamental requirements in public health engineering.

The late George W. Fuller, consulting engineer and past president of the American Public Health Association, was active in helping to define the field of the sanitary or public health engineer. In a paper² read at a general session of the 1925 meeting in St. Louis, he stressed the importance of education, applied research, and sound administration as means of bettering the performance of workers in this field. Three years ago Hyde contributed a careful analysis of the functions and opportunities of the engineer in public health work.³ Abel Wolman has repeatedly urged further expansion of public health engineering practice into unexplored fields^{4, 5}; and he has directed attention to the importance of coördination of levels of health services—federal, state, and local.⁶ Other thoughtful leaders in public health believe that a comprehensive reëxamination of the causal relationships and practical values in environmental sanitation is most promising as a guide to effective planning and administration.

This brief review of basic considerations suggests five major objectives for further advancement of public health engineering as a result of the Social Security Program:

1. An effective program of education concerning environmental sanitation which will make use of factual knowledge of public health engineering and effectively utilize educational facilities in health departments to reach the general public as well as special groups.

2. Professional education of public health engineering personnel through postgraduate courses in universities and by supervised field experience; and adequate instruction in the fundamentals of public health as a part of the undergraduate curricula of engineering schools.

3. A comprehensive program of research, both fundamental and practical, including studies of the relationship of environmental factors to human health, the administration

of state and local programs of sanitation and engineering methods in public health.

4. Organization and direction of federal, state, and local activities in environmental sanitation, in a manner which will unify the program, provide supervision and effective planning, use the qualifications of engineering personnel efficiently, and avoid unnecessary duplication of effort.

5. To develop and improve public health engineering procedures so as to increase their effectiveness and be conducive to further extensions of environmental control that may be justified on the basis of present or future knowledge.

The Social Security Act specifically provides for the attainment of these objectives. Its administration has emphasized special activities in health education, professional education of personnel, coördination of research with practice, and expansion of the scope of environmental sanitation. Large increases in the number of public health engineers and sanitation assistants have already been made. Public health engineering activities have been greatly extended and the ground-work has been laid for a coördinated approach to the more difficult aspects of environmental hygiene. Further progress appears to depend primarily upon the perspective, the initiative and the skill of those engaged in this field.

HEALTH EDUCATION

Popular health instruction in the fundamentals of sanitation is essential to advancement. Past experience has demonstrated that it is possible to interpret scientific facts and present them to the public in a manner which will elicit interest and coöperation. But to be effective such an effort must be well organized and specific. Specialists in health education have been made more generally available in states and in the larger local health departments. Their assistance can also be of great value in disseminating available knowledge concerning public health engineering practices.

The methods and materials used must be well adapted to obtain the interest of important groups such as municipal officials, industrial officials, property owners, engineers, architects, plumbers, equipment dealers, and a variety of organizations. Of particular interest are more recent efforts to expand health education by instruction in public schools. Teachers are better prepared to teach public health to children; they are prepared to utilize information provided by public health engineers and sub-professional personnel in sanitation related to the local school and community. A common weakness of public health engineering in the past has been failure to make known to others the full extent of its problems and accomplishments. With more adequate personnel and assistance general health education should be an increasingly productive field in this phase of technical service.

PROFESSIONAL EDUCATION OF ENGINEERS

From the standpoint of the future development of public health engineering the most important result of the Social Security Program is increased recognition of the necessity for professional education of public health workers. Guiding principles for the postgraduate instruction of public health engineers recommended by this Association are being followed quite closely in several universities.⁷ The educational facilities which are now available and progress in the education of public health engineers, sanitarians, and sanitarian assistants (sanitary inspectors) are to be discussed in a later paper on this program. It now seems probable that public health engineering will be developed as a well defined specialty of the engineering profession and that more adequate facilities for graduate study leading to degrees in this field will be provided.

The influence which the Social Se-

curity program may have upon the integration of public health instruction in undergraduate engineering courses is problematical but encouraging. The practice of engineering in almost any field has manifold public health aspects. An understanding by all engineers of the many conditions of environment which have an influence upon health and co-operation with official health agencies will be more and more necessary. Also, it seems apparent that an increasing number of engineering graduates will decide to specialize in public health engineering. An introduction to public health with emphasis upon its engineering aspects and fundamental courses in the biological and social sciences for all engineering students prior to graduation are particularly desirable. This should be considered as basic instruction and not be placed in the same category as the optional programs of study now offered by about 25 engineering schools for students who elect courses in sanitary or public health engineering.

The potentialities of such a development are impressive. It would tend to make engineers more conscious of public health problems in their own work and more coöperative with public health engineering activities. Then too, engineering graduates would be better able to decide whether they should specialize in public health engineering and would more fully realize the need for postgraduate study.

RESEARCH

We are constantly reminded that much available knowledge is not applied and yet a major difficulty in attempting to extend and improve the application of public health engineering is a lack of adequate information. Success in sanitation is peculiarly dependent upon indirect methods—promotion, salesmanship, education, supervision, stimulation, and leadership. Effectively applied these methods mobilize the re-

sources of others and multiply the efforts of the public health engineer. But recommendations of expenditures for adjustments of the environment must be supported by convincing data regarding their public health value. Public health engineering supervision implies approval of particular methods of environmental control. This requires factual knowledge that the prescribed methods will be effective. Professional leadership must be based upon demonstrated needs and sound proposals for improvement. The necessary fund of fundamental and practical knowledge can be maintained only by a well planned program of research.

The biological, epidemiological, and administrative phases of major engineering problems need to be studied concurrently, and this should be done in coöperation with federal, state, and local health departments. Laboratory experiments and demonstrations are essential; but more extensive studies representing the conditions of actual practice also are of greatest value. Studies of this kind can be conducted advantageously in connection with established public health programs where suitable public health engineering problems and improvements are available. The flexibility and coördination which characterize the public health program under the Social Security Act will prove invaluable assets in engineering research.

The spirit of research, as expressed in a well defined program, may be made productive as shown by past experience in the improvement of water supplies, sewage disposal, milk sanitation, and other established public health engineering activities. A better understanding of such problems and the initial impetus toward their solution came largely from official health departments. But after interest was aroused, and desirable objectives had been tentatively defined, a tremendous

amount of additional study and advancement were contributed by other public, private, and commercial agencies in these fields. There are at present numerous important public health problems which appear to be closely related to environmental factors concerning which the value and methods of environmental control are not known. For example, the problems of pneumonia and other respiratory diseases, infant and child health, air pollution, and the varied aspects of housing present interesting and interrelated questions of great practical importance. Comprehensive studies and the initiation of environmental control in regard to such problems are extremely promising both as a direct approach and as a means of stimulating more widespread interest and activity.

UNITY AND COÖRDINATION OF PROGRAM

From the standpoint of administration the state is the predominant subdivision. It is important that the state-wide program of sanitation should be unified to coördinate all public health engineering functions from the most technical and specialized services in state health departments to the routine performances of local units. This concept presupposes unity of responsibility for the state engineering services and for the engineering supervision of local sanitation programs. Confusion of responsibility in regard to local sanitation work can be avoided by a clear distinction between professional direction and administrative control.

The Social Security Program has accelerated the expansion of local health service and has stimulated specialized services, such as malaria control and industrial hygiene, in state and local health organizations. These services include major engineering activities requiring close coördination. In some instances these activities have been

separated from other state engineering programs. However, in several states, all state and local sanitation activities have been reorganized and made a responsibility of the state division of public health engineering. This plan has the advantage of combining the direct public health engineering services of this division with the planning and professional supervision of all other sanitation activities in the entire state. The preparation and experience of the state corps of public health engineers are utilized without interference with administrative procedures which is conducive to both efficiency and economy.

Obviously, the revision of present methods of administration in the various states will be a slow process. However, the policies of the Social Security Program which demand scientific planning and adequate professional guidance should lead to more unified and stronger state and local health programs. No standard pattern of organization can be applied. There is, however, need for less attention to organization and more attention to service. Regardless of the administrative boundaries which may be shown on an organization chart, the services of public health engineers with adequate preparation and experience will be recognized as indispensable in the administration of state-wide sanitation programs.

QUALIFIED PERSONNEL—AN AID TO EFFICIENT PERFORMANCE

In order that the public health engineering program may translate worthy plans into definite accomplishments, sound technics and high standards of practice are, of course, necessary. Waller⁸ has aptly compared environmental sanitation to the construction of a bridge or "skyscraper." The health officer may be compared with the architect; he studies the problem and prepares a functional plan of sanitation which will meet the essential needs and

be in harmony with related conditions. The public health engineer is responsible for the details of the plan, specification of methods and materials, and direct supervision of the sub-professional workers who assist in carrying the design to completion. The usefulness and stability of an engineering structure are based first of all upon demonstrated needs, sound economics, and competent design. However, in environmental sanitation adequate qualifications of both professional and sub-professional personnel are essential to the effectiveness and stability of the program.

A high level of minimum qualifications for public health engineers and sanitation personnel has been adopted by the Governing Council of this Association. Some may think that the qualifications suggested are too high to be generally attainable, but it should be recalled that about twenty years ago the standards of quality for drinking water on interstate carriers adopted by the U. S. Treasury Department were criticised as too stringent to have general value. Although these standards now are even more exacting they are universally accepted by public health officials in this country. Nearly all public water supplies far surpass the minimum requirements, and these standards of quality are considered practicable even for private water supplies and swimming pools. The unattainable standard of today becomes the accepted minimum of tomorrow.

It would be a great mistake to set our ultimate aims for qualified personnel too low or fail to use every advantage offered by the Social Security program in this direction. Nothing is more discouraging or uneconomical than to attempt to obtain good work with incompetent workers. Hyde's study in 1935³ indicated that there were "probably less than 25 public health engineers regularly employed in 21 county-unit or district health de-

partments in 10 states." As of December 31, 1937, coöperative state and federal budgets included 159 whole-time engineers employed by local county or district health departments in 21 states. Practically all of these have completed at least a short course of postgraduate instruction in public health, and an increasing number are being enrolled for a full year of graduate study in public health engineering. This indicates that in 3 years there has been more than a six-fold increase in the number of public health engineers in local health departments, exclusive of purely municipal departments; and more than double the number of states having at least one local department in which engineering supervision of sanitation has been provided. Such rapid progress in the local employment of graduate engineers and in arrangement for their professional education under the Social Security Program is merely one indication of the possibilities for the future.

Public health engineering has advanced rapidly and results have been obtained wherever responsibilities have been assumed and facilities for service provided. Effective engineering methods have been devised, more direct administrative procedures have been employed, and more competent personnel has been developed. The rapid expansion of service under the Social Security Act is coupled with a responsibility for maximum results in the use of funds to justify a continuation of the facilities which have been made available. This will result in more specific and efficient application of public health engineering knowledge and therefore in greater professional prestige and individual opportunity.

THE opportunities of the school physician are so unique that they merit the envy of the classroom teacher in other subjects. Our teaching is done by a combination of the classroom and clinic method whereby the learner is at once the object of the demonstration and the beneficiary of the method. What could be more ideal? How much simpler the teaching of mathematics would be if,

each time the student learned a new equation, he could be relieved of a distressing physical condition. How much simpler would be the English teacher's job if students consulted him with the same motives of personal concern and the same receptiveness to instruction as they have when they consult the college physician.—Charles E. Shepard, M.D., *Journal-Lancet*, Feb., 1939, p. 70.

Preparation of the Nurse of the Future*

LEAH M. BLAISDELL, R.N., F.A.P.H.A.

*Assistant Director—Personnel, Henry Street Visiting Nurse
Service, New York, N. Y.*

NO one who keeps in touch with current trends in public health can fail to see the rapidly growing tendency to accept greater if not complete responsibility for the health of the people of this nation. Assistance in influencing the economic, housing, genetic, and nutritional factors underlying health problems are among the newer activities which now engage its attention. Interest in a much greater scope of disease problems exists than even 10 years ago. So logical a part of public health does the provision of adequate medical and nursing care of those who are ill now seem, because of the consequences of its lack, that its inclusion in community health programs is rapidly becoming a major issue. Just how this will be accomplished is of course one of the most provocative social problems of the hour, but that in most communities public health administrators will be responsible for the coordination of efforts and the machinery to provide that not otherwise cared for, will be doubted only by those who believe a non-medical type of agency can more adequately administer this service. The health

administrator will, if this is true, study with increasing intensity all of the factors that are involved in this care. He will conscientiously investigate all morbidity situations and, while continuing to apply this epidemiological methodology toward their prevention, will, on the other hand, survey the amount and quality of care available, what is lacking, and how it can be provided or strengthened.

If this is a true picture of the future, and our N.O.P.H.N. definition of public health nursing which designates our responsibility as that of giving nursing assistance in the whole public health program, is sound, then we shall see that the community and its health administrator are going to need and expect nursing directors and supervisors who can give them expert assistance in analyzing the total nursing picture in their community. Not just the picture of the need for and the kind and quality and production of public health nurses but of institutional and private duty and practical nurses, in order to have that community or area adequately nursed. They are going to become, or should be helped to become, intensely interested in how all of those nurses are prepared and how that preparation could be improved so that every nurse will contribute to the improvement of the health of the community.

* Read before the Public Health Nursing Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 25, 1938.

It would seem therefore that there will be a great need for nurses with increasingly broad understanding of the whole social and nursing situation to fill these leadership positions.

Now let us try to think what we really want of the staff nurse of the future. Two avenues of divergence from the present average nurse present themselves. One is in the direction of more automaticity, i.e., training merely in skills and technics. The other is in the direction of real education in basic principles of science and sociology which will lead to self direction and creativeness. It is easy to sympathize with the many who favor the former divergence because of the greater ease and rapidity of preparation of nurses of this type and especially since many communities at present do not appreciate the deeper aspects of having their community "well nursed." A little reflection, however, by those experienced in public health convinces them that those communities probably need the most expert nurses to understand and break down prejudices and give leadership into newer ways of thinking. And if we want a large area such as a state or the nation to be "well nursed," I submit that there is but one way of having it done and that is to have in each community or health area nurses who have a broad conception of a vital community health plan, a scientific understanding of its component parts, who are capable and interested in studying what contribution nursing can make to that plan, and who have ability to assist in leading their community into carrying the plan into action. Any nurse who has been in position to compare nurses from a state or national horizon is convinced that in every area from New York to San Francisco there is a crying need for nurses of this ability, integrity, scientific knowledge, and spirit of service.

Possibly one reason for confusion as

to the trend we should take has arisen because well prepared nurses have been used to carry on functions which could be accomplished as well by those with little or no training. In the better thought-out nursing programs (both public health and institutional), this largely has been avoided by use of volunteer assistance. In the institutional field the use of a subsidiary worker such as New York State's new licensed practical nurse is an approach to that problem. It is not beyond conception that she may also be used in the community nursing service. If so, a plan should be made to have the two work hand in hand as nurse and nursing assistant. But let us make no mistake that our crying need is first for nurses who can plan and organize and nurse their area before we consider another group of paid assistants to amplify it.

Another factor of resistance to that type of nurse has been confusion of our medical associates who feel we are desirous of replacing them in medical functions. It has been my experience that the best equipped nurse is least guilty of creating that impression. She sees so much to be done in her nursing province that she runs less chance of trying to take on the medical officer's or physician's job herself.

If we really want this kind of staff nurses we must help the community to understand that the type of program suited to develop such leadership over the long range cannot always produce workers who are immediately skillful. We will have to see that potentially good material is patiently protected during this learning period in order that their ultimate contribution may be great. We must encourage this type of preparation of young women in sufficient numbers that each time we find such a promising person we shall not need to snatch her from field work for a supervisory position (often prematurely for her own good) and lose the benefit of her con-

tribution to improved field work, an inestimable loss for which the only correction I can see at present would be the return of every administrator, instructor, or supervisor to field work periodically. Incidentally I believe some new and better emphases in public health nursing would soon result.

How can such nurses be prepared? One way is to influence and assist those responsible for postgraduate courses. Fine! Do we do it? Too infrequently. When they endeavor to be more selective of their students we beg for exceptions or complain of their being too strict in their regulations, and then blame the college because all their output is not suitable material for our needs. We fail to keep in close touch with the college and tell them just what we shall expect of the nurses they educate. We have an increasing tendency to define our standards for postgraduate work in terms of procedures to be followed rather than goals to be achieved. We want a transformation in the nurse to be accomplished in a period of time too brief to give the basic underlying fundamentals. Then, too, we are very easy going employers, too unanalytical and avocal about the failures. From such reports the university could learn how to improve in the future. We do not plan generously for areas and personnel to give the field experience necessary to round out this preparation. This is particularly true of official agencies who are prone, not even to assist the nonofficial agency in so doing, saying they are too busy or too poor, and yet criticising the new appointees they accept because they do not have the health department point of view—merely a V.N.A. outlook.

But even if we corrected all these faults and were paragons of virtue as far as postgraduate education is concerned, I think there is not a public health nursing course director who would not say that still her greatest

problem is finding students, with a sound basic scientific education and clinical experience upon which to build. If you do not know what I mean just try to inspire and teach a group of potential public health nurses how to assist in a communicable disease, tuberculosis, or syphilis program who have never had any experience in that field. I am not sure that Mary Beard will not go down in history as the outstanding public health nurse of our times in her insistence that the place to strengthen nurses for community work of the future is in the basic nursing course, and that all nurses need this broad understanding of community health.

But what do most of us in public health do about that? Mostly stand aside and consider it out of our province. Only a very small percentage of the public health nursing group belong to the National League of Nursing Education, which membership is the logical way to help.

Fortunately the few who have belonged have been sufficiently expressive of needs that there is every evidence that nurse educators now have their ear attuned to them. They are working arduously to find better ways of attracting and selecting young women with the basic personality qualities suggested above. The colossal reconstruction of the curriculum for schools of nursing¹ published last year recommends advanced educational standards of one or two years beyond high school and suggests liberal pre-professional requisites which will add to the student's general knowledge, her maturity of thought and judgment, and her cultural development. In the professional curriculum provision is made for greatly strengthening the social, biological, and physical sciences; emphasis is placed from the very beginning upon all nursing as health conservation; upon the family as the agency for promoting health,

and the child as the most malleable recipient; upon nutrition; upon groups of illnesses (including mental) now more amenable to control; upon the teaching function of the nurse; upon her own health and the enrichment of her own living. Wherever this curriculum can be followed a new generation of nurses will surely rise to challenge us.

But, as has been ably pointed out, there are a great many handicaps to its universal application. Ruth Hay classifies them as economic and educational.² Outstanding among the economic problems is the fact that the school of nursing is under control of the hospital, an institution whose primary interest is service rather than education. To be sure, the hospital is necessary to a school of nursing as a practice field, but there are great disadvantages to a control that accepts unfit students in order to fill a quota, keeps questionable or frankly undesirable students because they lend an extra pair of hands and feet, maintains a school in a hospital abominably lacking in variety of clinical experience which the nurse will later meet in any normal community, skimping the school budget for fancy equipment, luxurious appointments in private rooms, or for attractive landscaping. These practices are so universal that they are almost acceptable to us in public health who could, if alert, find many opportunities to lend excellent outside assistance to the nursing school director who is a voice crying in the wilderness to her board and community for the chance to conduct a real school of nursing or discontinue it and employ a graduate staff. A second economic problem is lack of endowments or governmental subsidy such as colleges of medicine, education, or other professions enjoy, which would permit enrichment of the program within a cost not prohibitive to the average young woman.

Outstanding among the educational problems are (1) students too immature to assimilate this service, (2) resistance of the medical profession to "too much training," (3) lack of preparation of the faculty to incorporate the health point of view of which they are frequently unconscious because they have not had experience in that field, (4) scarcity of public health nurses willing and equipped to assume positions on nursing school faculties, and (5) disinterest or lack of adequate preparation of public health agencies to provide field experience for rounding out this education.

Could we as public health workers help in any of these problems? Immeasurably! In the first place, participation in the local League is indicated; a careful study of the new *Curriculum Guide* would be good preparation for a conference with the nursing school directors in our area, at which we frankly ask if there are any ways in which we can help. And if in the meantime we interpreted this enriched program to our health administrator (who should appreciate its potentialities) and motivated him to interpret and support it with other physicians in the community, it might smooth considerably the road to its adoption. We need not accept a membership on their nursing school committee which *might* result, but we can use every opportunity to interest other influential community members in these nursing education problems; possibly we could spare or help them to find an experienced and qualified public health nurse who would be interested in a faculty position, or perhaps we could arrange to assist in the teaching program on a part-time basis ourselves.

We may not be able to offer an affiliation for students in our agency, but we could plan well ordered short observation periods for each nurse or possibly allow key members of the faculty to

have a 4 or 6 weeks experience in our organization. Perhaps this could be arranged on an exchange basis, lending our superior nurses who would give as well as gain. Both groups should profit by such a plan. There is no dearth of possible ways in which we could assist in better basic preparation of the nurse of the future, but there has been a lack of assumption of responsibility in that field which I feel can no longer be condoned if we are truly interested in the nurse of the future who will or will not see that her area is well nursed.

And now a few convictions concerning the actual preparation of the public health nurse of the rather near future, a problem you and I are meeting today. One of the most important contributions we could make would be to be highly selective of the nurses we employ. We could strengthen all nurse educators if we refused to retain nurses who did not give evidence of sound integrity, sufficient cultural background to meet people in all social stations with reasonable ease, or who could not speak the English language correctly or compose an acceptable letter. Likewise, we could register our disapproval of schools lacking in strong science courses, teaching instruction, or enriched clinical experiences, by not accepting their graduates until they have strengthened these deficiencies. Alumnae members so counselled soon take this information back to their alma mater.

As I have previously stated, the burden of this responsibility for field introduction falls on the nonofficial organization—one of their great contributions in my estimation. Lest those reared in that environment get the one-sided view of public health, these organizations must turn their attention to having their faculty and supervisors persons who have experienced different types of public health nursing; official as well as nonofficial,

rural as well as urban, specialized as well as generalized. Increasingly they should be persons with broad interests who are thoroughly active citizens in their own community and keenly attuned to professional problems through their participation as well as membership in professional organizations.

Not only must these nonofficial organizations see their true relationship to the community health plans—i.e., doing what the official agency is not yet prepared to undertake, but the official agency must demonstrate greater appreciation of the help of the nonofficial agency, be willing to talk over their plans frankly and discuss freely where the nonofficial agency can contribute most. They must trust that group well enough to help them work out the student or new staff introductory program, sharing as freely as possible opportunities for observation or participation within its program.

More emphasis must be placed on the goals and objectives of the organization rather than on the technics of procedure. Given a carefully selected nurse, well grounded in medical and health situations and basic principles of nursing care, take time to interest and inspire her in what can be done about them, and then challenge and encourage her to work out the best way to influence their improvement in a small area for which she is to be accountable, and one will rarely be disappointed in having a veritable dynamo of ideas and actions of a creative and coöperative nature. If she can learn that the supervisor is a sympathetic person with whom she can talk these over, who will protect the community and herself from the utterly unsafe or impossible parts of her plan but who will let her try and fail in a few from which she will learn lasting lessons; if she knows the supervisor will help her evaluate why the failure occurred and how it may be subsequently avoided, zeal and every-

day freshness in tackling even routine duties will result and a group of nurses with ability to contribute to better and easier outcomes in public health will be prepared. True, the supervisor will become less prominent as a "manager" of her district but she will experience a new and deeper satisfaction of the real teacher whose greatest aim is to produce proteges greater than herself, and incidentally she will save herself many details of administration.

A graduation and rotation of responsibilities from simple illness care through health teaching in families to teaching in groups, to making community contacts, to being responsible for keeping the whole staff well informed on trends in some certain phase of the work, to assisting in teaching students, until all has been given and gained of which the organization and nurse are capable, is a sound plan of preparation. The nurse should then be guided into seeing that her next step should be a broadening of her experience in another type of agency.

Out of such plans should grow nurses capable of developing into the supervisory or administrative positions which are to demand so much of the nurse of the future if she cares to take on this added responsibility for others. I hope, however, that many of this type of nurse are going to find the joy of the "master touch" in staff work, and with a fine preparation, a thirst for constantly reinforcing it with the new, a broad understanding sympathy with all the different organization approaches to solving the community health problem, and with a real interest in participating in professional affairs, will seek the niches where they feel they can best serve and demonstrate over long fruitful years the results of artistry and devotion in a community nursing service.

Interpreting the Physician and Making Him a Part of the Health Education Program*

MARY P. CONNOLLY, F.A.P.H.A.

*Director of Health Education, Detroit Department of Health,
Detroit, Mich.*

PERSONAL health education endeavors so to motivate human beings that they will follow such practices, and obtain such services, that an optimum of health will result.

With the exception of a few personal practices, most information which will contribute to health must be obtained from the physician to meet individual needs. Practising physicians, by and large, are an inarticulate-group, except, if I may add facetiously, in medical society meetings. They are doers, and not explainers, they say. This has come about to some extent as a hang-over from the days when the practice of medicine was reckoned by many as a sort of magic which the public did not expect to understand.

With freer communication, and an enlarged vocabulary, the average person wants to know what the words so freely used by physicians and others dealing with the practice of medicine mean, before he is willing to submit to procedures for which these words are used. As an example of this, any person who comes in contact with large numbers will realize how confusing just this

matter of "blood test" can be to the average person. A blood test may mean a Wassermann or a Kahn, or it may mean an estimation of the red and white blood cells, or it may mean blood taken for any number of other laboratory procedures.

Probably the idea of magic has remained attached to any procedure which has to do with the blood more persistently than to most practices in medical science. Need we be surprised then if the man in the street becomes over-responsive to the advertising of quacks which convince him that the source of his complaints can be discovered by placing a few drops of blood in an electrical contrivance? Likely he has had a leukocyte count; he may or may not have had a Wassermann or a Kahn; but in all probability some reputable physician has taken blood for some simple diagnostic procedure about which he has failed to educate the person involved. This is but one of the many instances which the everyday man experiences many, many times. A correct diagnosis of his illness may have been made as a result of the procedure, and he may have recovered from his illness, but he has learned little from it which will enable him to respect scientific services.

* Read before the Public Health Education Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 25, 1938.

There is little doubt that much of the health education of the future will have to come from the practising physician at the time he sees his patient, because preventive medicine deals more with the ways of living than with remedies. In the meantime, the established organizations which promote health education will have to find ways to provide this education. Those of us who deal with mass education ponder long and hard how specific education of this sort can be given to large numbers. The newspaper, radio, and printed matter can point the way but it requires much more than this general information to enable persons to think through their own problems and obtain what they need on one hand, and avoid becoming hypochondriacs on the other.

It is very easy to say to a community "Every child must be protected against diphtheria." It is easy again to tell the parents how this may be brought about, and the steps to be taken to ascertain whether the child has retained the protection; but if we stop here without teaching these parents, in a general way, what happens in the child's body when the preventive treatments are given to him, we have not established a trend of mind which will prevent the parent from using any number of so-called specifics which are recommended by advertisers in the printed page, and on the air. The recommendation of the promoter of cure-alls is as valid to this man as ours.

Every person here has been confronted with the confusion in the minds of average parents regarding the so-called "shots" which their children have received. Too many of these people believe that diphtheria prevention treatments protect their children against whooping cough and scarlet fever, as well as diphtheria. In our efforts to reduce diphtheria cases and deaths, have we not forgotten that most persons have little information

regarding the specificity of the recommended procedures? We, and I include physicians, assume that this person knows what we are talking about when we say "diphtheria prevention," and 99 per cent of his kind do not.

An intelligent woman stopped me, after a meeting recently, to tell me how disturbed she was because a few days before she had taken her child to a pediatrician for a repeat Schick test and he told her that the test sometimes raised the blood titer. Her concern was that the physician was doing something to her child's blood, and how would it affect him in after years.

Stuart Chase, in his *Tyranny of Words*, which is a tyranny in itself, has advanced the idea that words as they are now understood separate us rather than bring us together, and I believe that this is particularly true in much of the vocabulary used by physicians and many health workers.

Advances in a democracy can be made only on a basis of education. A health dictatorship varies not one bit from a political dictatorship. The public must learn that it is their bodies and minds that are concerned, and that their happiness and security depend upon the care of their bodies. They must learn what intelligent care means, and the advantages and limitations of medical science, if they are to choose wisely. This learning will come only when we have given them an idea of body processes and medical procedures.

Health education in the early days was centered largely upon communicable diseases because they were the immediate problems of health organizations. Health education has played a large part in the control of these diseases, and these same organizations now are turning their attention to other conditions which have supplanted the communicable diseases in the list of principal causes of death.

The education required to affect the

degenerative diseases is much more difficult than the mass education which produced such good results with the communicable diseases, because it involves morbidity as well as mortality, and affects the economic life of the people, as well as their happiness. The prevention and care of the nutritional and degenerative diseases requires skill of diagnosis which involves new procedures which are costly and time consuming, and can be obtained only from a physician.

Without going into the economics of this situation about which the health educator has little to do, the responsibility for supplying education which will prevent these disabilities still is with us. An interpretation of procedures is vital and probably will be to an increasing extent as medical science advances.

Is mass education enough for this? I have doubted it for a long time. I believe we must search diligently for opportunities for personal contact—that face to face presentation which will give us an opportunity to learn what people think and how they interpret the education which we plan for them. A number of discussion groups in any community will provide this way of interpretation which will reach thousands who would not be interested in our printed matter or who never will attend meetings.

Those who lead discussion groups must be aware of the need for a common language or they will only add confusion to an already confused state.

Our printed matter, our radio talks, and our newspaper releases all need careful study in order that the many will see scientific medicine not as an abracadabra but as a reasonable procedure built upon their body needs and operation.

You will listen to discussions of technics for supplying this interpretation to the public during this meeting and

these technics will be adapted to the various communities represented by those who are here because the job for the present rests with them. How can we help the physicians of our communities take on this job which so obviously belongs to them?

It is our frequent error that we plan a program and then ask physicians to promote it for us. We go on the assumption that we know what is good for the people and that the physician will benefit from the program as well as the persons he serves.

Somehow, all persons like to have a hand in shaping "our duty." Physicians are not exceptions to this rule, and we do "our duty" with much more relish if it is palatable and we are sold on it.

Prominent physicians in most communities are asked to assist health organizations in presenting radio material, in giving talks to groups, and in many other activities. But how about the neighborhood physician, the general practitioner, who sees the largest number of the sick and near-sick in any community? What efforts are we making to help him be a part of the health education program? Because he must be available at all hours of the day and night, he has less time to read and to attend medical conferences, and because his income is less than his specialized brethren he has less money to spend for postgraduate education.

Do we keep the general practitioner informed as to our program through frequent and carefully planned communications or do we wait for him to know about it from the newspaper, radio, or his patients?

There probably is no better investment of health education funds to be found than that intelligently planned to keep physicians informed. The personnel of the organization is expanded a hundredfold by each physician who recognizes his part in the field.

Medical societies and organizations send very tiresome and uninteresting communications to physicians whose interest they wish to obtain. The rule with these communications is that they shall be several pages in length, single spaced, with little or no margin, and that the mimeograph will be cleaned after the communication, and never before.

There is not much doubt that we talk about the subject in which we are currently interested. Physicians are not exceptions to this rule. With this in mind, can we not find places for them in our program of interpretation in order that they may learn a language that will be understood by their patients, and that they may delight in watching the appreciation of these patients when they are recognized as intelligent persons.

If we are to elicit the interest of physicians, we must keep them informed as to the problems of our community; we must ask their advice as to solving these problems, and, since written communications are the quickest way to do this, our missives must be attractive from a physical standpoint, and psychologically appealing.

There are many bits of health education which the neighborhood physician can do for small groups. In the early days of our diphtheria prevention program we sought opportunities for the dissenting or uninterested physi-

cians to talk about it. Printed matter was mailed to them giving them the details with which they were not too familiar and they were asked to talk to small groups in churches and in schools about the need for protection against diphtheria. They came through to a man, and reports from patients that the physician did not believe in immunization ceased.

In a county in Michigan, the health officer invites one of the practising physicians of his community to take his place when he is to be out of town for a day or two. The temporary health officer learns many things about health conditions in the county during his brief period of responsibility, and his interpretation of activities becomes excellent health education for his own patients.

SUMMARY

Health education regarding procedures and practices must come from the physician at the time the patient is seen.

Medical terminology must be translated into a language which can be understood by the average man.

Physicians shirk this responsibility largely because in the past it was not expected of them.

The experience of meeting groups and answering their questions will give the physician an appreciation of the confusion found among all classes of people.

The health education activities of an organization will be effective only when local physicians have a hand in planning and helping to promote them.

Use of the Phosphatase Test in the Control of Pasteurization*

PAUL F. KRUEGER

Chief Sanitary Officer, Board of Health, Chicago, Ill.

AT the last Annual Meeting of the American Public Health Association, I reported on the use, by the Chicago Board of Health, of the phosphatase test for determining the efficiency of pasteurization of the milk and cream sold in the city. The chief cause of improperly pasteurized milk was reported to be dishonesty on the part of some of the operators of the equipment. I gave a description of the methods used in greatly reducing errors of pasteurization from this cause.

The number of samples of improperly pasteurized milk and cream which were subsequently found was very small. Investigations disclosed that the cause in the majority of these samples resulted from the use of improperly constructed pasteurization apparatus or the use of apparatus so constructed as to permit readily of improper operation, which was particularly true of the inlet and outlet valves with which the pasteurizer vats were equipped. In 88 milk pasteurization plants, 212 outlet valves and 146 inlet valves were defective when compared to the latest standards of the U. S. Public Health Service for the construction and operation of such equipment. The important requirements for plug-type leak-protector

pasteurizer valves may be briefly summarized as follows:

A. All grooves shall be at least $3/16''$ wide and at least $3/32''$ deep, to prevent clogging and promote drainage.

B. All single leak grooves and all mating leak grooves when mated shall extend throughout the entire depth of the seat, so as to divert leakage occurring at all points throughout the depth of the seat, and so as to prevent air binding.

C. Washers or other parts shall not obstruct leak-protector grooves.

D. A stop shall be provided in order to guide the operator in closing the valve so that unpasteurized milk may not inadvertently be permitted to enter the outlet line or the holder, respectively. The stop shall be so designed that the plug will be "irreversible" if the plug is provided with any grooves or their equivalent unless duplicate, diametrically opposite grooves are also provided.

E. All leak-protector valves shall be installed in the proper position to insure the proper functioning of the leak-diverting device.

1. The design shall protect against leakage in every position of the plug which prevents the flow of milk, *i.e.*, every "closed position."

2. In the case of outlet valves, the design shall, in every "closed position," prevent the accumulation of unpasteurized milk in the plug channels.

F. There shall not be more than $5/64''$ between the "just closed" position and the functioning of the leak grooves.

G. Pipe lines between the inlet valve and holder shall be as short as practicable, and shall be sloped to drain.

H. In cases where the milk in the vat is apt to submerge the inlet pipe and thus prevent its complete emptying when the inlet valve is closed, the inlet line shall be pro-

* Read at a Joint Session of the Laboratory, Public Health Engineering, and Food and Nutrition Sections of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 28, 1938.

vided with automatic air relief located either at the valve or otherwise, and so designed as to function in every closed position of the valve.

I. Outlet valves on pasteurization holders shall be close-coupled whenever the outlet penetrates the holder below the milk level.

J. Outlet valves shall be operated so that they are fully closed during the filling, heating, and holding periods. Inlet valves shall be operated so that they are fully closed during the holding and emptying periods.

In order to prevent the possibility of improperly pasteurized milk occurring from the use of defective equipment, owners of milk plants in which valve defects were found were advised to make the necessary changes, which they readily agreed to do. In a few instances the changes were made by the individual dairymen, but in the majority the work was done by a mechanic selected by the manufacturer of the valve, and supervised by a representative of the Board of Health. The cost was exceptionally small, although much of it was done in machine shops, and the milk plant operators coöperated wholeheartedly in making the improvements, with the result that all necessary changes were completed.

The most common defect found in the valves, both inlet and outlet types

and regardless of make or design, was that the grooves were too small to function properly. About one-third of these valves had the entire leak groove in the valve body. The defective grooves were corrected by putting the valve body in a shaping machine and cutting the groove to the proper size with a tool sharpened at the end to a semi-circle $3/16'' \times 3/32''$. (Examples of this defect and the method of correction are shown in Figures 1 and 2.) This would require about 45 minutes' work for a single valve. If these were several identical valves, the time per valve would be reduced considerably, since the machine would not have to be reset for the succeeding valves. Where the groove to be enlarged was in the valve plug, a different method was used. The plug was put in the chuck of a lathe. An electric drill was mounted on a sliding tool rest. A $3/16''$ reamer was rounded at the end to form a semi-circle $3/16'' \times 3/32''$ and put in the drill chuck. The drill on the tool rest was moved back and forth, the revolving reamer milling the groove to the proper size. (See Figures 3 and 4.) With this set-up any kind of groove in the plug could be cut or enlarged. A plug

with a pair of grooves, either full or partial length, could be set up in the lathe and milled to the proper size in $\frac{1}{2}$ hour.

Another common defect found in inlet and outlet valves was that the valves did not prevent the accumulation of unpasteurized milk in the plug in all closed positions. In the cases where the grooves were in the valve body only, the plugs were made self-draining in all closed positions by cutting away metal from the plug to form two opposite lower corners of the hole in the plug, so that this cut-away would meet the leak-groove in the just closed position and drain the plug. (See Figures 5 and 6.) In a few cases the center of the hole in the plug would ride past the leak groove in the fully-closed position, making it necessary to cut away metal to create the additional two lower corners to make the plug drain completely in the fully-closed position. This cutting away could be done with a round file in about 20 minutes for each plug. (This is illustrated in Figures 9 and 10.)

Another common fault found was in valves which were of a type having grooves in the plug which started at the

lower and upper points of the hole in the plug on each side, and extended far enough up and down the plug to meet a cut-away section of the valve body. Enlarging these grooves to the proper size also, in many cases, corrected the defect of the plug not being self-draining in all closed positions. When enlarging the grooves did not make the grooves in the plug meet the cut-away notch in the shell soon enough, it was necessary to file the notch larger. (See Figures 7 and 8.) Sometimes the groove in the plug did not extend far enough up or down to meet the notch sufficiently to allow a passage $\frac{3}{16}$ " x $\frac{3}{32}$ ". In these cases the grooves were lengthened as well as deepened and widened. As a rule this type of valve was readily improved because it did not necessitate removing the valve body from the pasteurizer.

One disadvantage of this style of valve is that it has a short stop-pin in the plug and two pin-stops screwed into the shell. The stop-pin wears readily into the pin-stops, thereby shifting the "fully-closed" position over far enough so that the grooves in the plug do not match fully with the cut-away notches in the valve body. Therefore, a valve which may comply today may not comply in a short time, due to wear. The length of time, of course, for this wear to occur depends on the use the valve receives. Broken or loose pin-stops and stop-pins was a common thing.

The grooves in some valves were located in the shell in such a position that if the plug was not operated in the quadrant within the stop-pins and the plug was in the "just-closed" position, the hole in the plug would be about $\frac{1}{4}$ " from the leak groove, thereby making it possible for the milk to short circuit through the hole in the plug to the outlet line. This defect was overcome by making the plug irreversible by putting another pin-stop in such a position that

if the plug were reversed it would be impossible to open the valve. (See Figures 11 and 12.)

A few irreversible outlet valves had the leak grooves located in the plugs in such a position that they were between the hole in the plug and the outlet hole in the pasteurizer in the "fully-closed" position, the mating grooves being in the valve body. This design would prevent the accumulation of unpasteurized milk in the plug when in the "fully-closed" position, as shown in Figure 13, but when in the "just-closed" position, the one leak groove lies in the opening of the pasteurizer and does not function, making it possible for unpasteurized milk to accumulate in the plug or leak into the outlet line. (This is illustrated in Figure 14.) This defect was overcome by extending the groove, which does not pass the outlet hole of the pasteurizer, the full length of the plug to the proper size, and filling the other groove with tin or brass. A new groove was cut in the shell, the distance from the outlet hole of the pasteurizer being equal to the size of the diameter of the hole in the plug, and a corner of the hole in the plug was filed away to make it self-draining in all "closed-positions" (see Figure 15). When this same defect occurred in a reversible valve, both grooves in the plug were filled and new ones cut in the shell. Valves with four grooves in the plug and mating grooves in the shell were modified in the same manner. In the case of inlet valves it was necessary to fill both grooves in the plug because enlarging the one groove to the proper size would bring it too close to the hole in the plug and to the outlet hole to the pasteurizer. To remodel a valve which requires the filling of two grooves, cutting two new grooves, making the plug self-draining in all closed positions and installing a pin-stop and stop-pins, requires about $2\frac{1}{2}$ hrs. in the shop.

Another type of valve has a hollow

plug which is inserted through the bottom of the pasteurizer, with two small holes that match with two holes in the shell inside the pasteurizer and one large hole that matches with a large hole in the shell below the pasteurizer and the outlet pipe in the open position. The leak groove runs horizontally around the plug or shell between the upper two inlet holes and the lower outlet hole diverts the leakage to the lower chamber of the plug and then out of a leak hole in the shell to the

floor. This leak hole was not always located in such a position as to drain the plug in all closed positions, as illustrated in Figure 16, so it was necessary to extend this hole to meet the hole in the plug in the "just-closed" position, or to file a groove in the plug. (See Figure 17.)

Another defect noted in this valve which classifies it as not completely leak-proof, was the fact that through usage the plug may be scratched or a flat side develop due to much handling. When this scratch or flat side occurs on the side of the plug that lies in the outlet of the valve in the closed position, leakage will run down this scratch or channel into the outlet line, rather than around the horizontal groove into the lower chamber and out the leak hole. These valves were made self-draining in all closed positions to prevent an accumulation of unpasteurized milk in the plug, but, in addition, the outlet pipes are required to be disconnected during the filling, heating, and holding periods. It is then steamed just before being opened.

Very few inlet valves had air vents or vacuum breakers, so, as a precaution, air-vent grooves were put in the plugs of all inlet valves on the pasteurizer side which would be operative in all closed positions.

Most outlet valves had stop-pins and pin-stops, but about 25 per cent of the

inlet valves had to be equipped with them. This was an easy matter. Holes were drilled and tapped, pins threaded and screwed in. Threaded pins were found to be more permanent than sweated or driven ones. Practically all bottom plates afforded ample drainage and defective ones were readily improved.

From the work done on these valves, we found that the vertical leak groove was most desirable. A horizontal groove is satisfactory only when leakage occurs in a vertical direction, as in a flow-diversion valve.

Due to the ease with which stop-pins can be broken or abused, we found the most desirable arrangement by having the shell cut away on one side, thereby eliminating two pins. This also makes the valve irreversible.

Inlet valves should be self-draining in all closed positions because, with an accumulation of raw milk in the plug, it is possible for this milk to leak into the inlet line leading to the pasteurizer through a deep scratch such as may be caused by turning the valve with a piece of abrasive substance in it.

The result of this equipment improvement program has been a definite decrease in the number of samples of milk found, which the phosphatase test indicates not to have been properly pasteurized.

SUMMARY AND CONCLUSIONS

The phosphatase test, when originally applied, showed a relatively large proportion of samples of milk and cream to be improperly pasteurized, due principally to improper construction and operation of pasteurization equipment. An intelligent study by the health officer of the reasons for pasteurization failure makes it possible for him to insure the use of proper pasteurization equipment and methods to the end that errors may be very nearly eliminated.

Application of the Phosphatase Test to Creamery Butter*

G. W. SHADWICK, JR., AND M. E. PARKER, F.A.P.H.A.

Beatrice Creamery Company, Chicago, Ill.

ACCURATE control of the temperature and the time of heating in the pasteurization for dairy products is essential to good public health practice. Formerly the only proof of an adequate treatment was the chart of the recording thermometer. This in turn depended not only upon the integrity of the operator, but also upon the accuracy of the instrument itself. Therefore, the development of a dependable laboratory test to indicate the thoroughness of pasteurization has been widely welcomed and to date the phosphatase test appears to have the most promise as an effective laboratory method for the control of proper pasteurization.

The original phosphatase test was developed by H. D. Kay and W. R. Graham in England in 1935.¹ These workers found that a phenol value of 2.3 Lovibond blue units or less produced in a sample of milk treated with buffered substrate and incubated for 24 hours at 37° C. would be indicative of properly pasteurized milk which had been heated to 145° F. and maintained at that temperature for 30 minutes. Kay and Neave² later reported that for the American conditions of pasteurization at 142° F. for 30 minutes, a 2½

hour incubation was sufficient. Data collected by Storrs and Burgwald³ in their studies of the phosphatase test under commercial conditions indicated that 2.3 Lovibond blue units as reported by Kay and Graham for samples incubated 2½ hours constitutes a proper standard for milk pasteurized at 143° F. for 30 minutes.

These standards which have been developed for the holding methods of pasteurization are not practical to apply to creamery butter practice inasmuch as the vast majority of creameries in this country use the flash method of pasteurization due primarily to volume considerations. Last year Parker and Brengman⁴ reported that for cream pasteurized under a variety of commercial conditions of "flash" pasteurization, a temperature of at least 185° F. for 2 to 3 seconds is necessary in order to obtain a maximum reduction of bacteria as determined by the plate method. Incidentally in their studies, a preheating period of 30 seconds was used to raise the temperature from approximately 100° F. to the pasteurizing temperature. Pasteurizing temperatures below 185° F. were found to be not as effective as temperatures of 185° F. or higher. The conditions of high-temperature short-hold pasteurization of 160° F. for 15 seconds has never been studied in the pasteurization of

FIGURE I

cream for butter making. Therefore, our studies have centered upon the establishment of standards for the phosphatase test which are applicable to cream for butter making which has been heat treated by "flash" pasteurization.

Our first problem was to duplicate, on a laboratory scale, the practical conditions prevailing in the so-called "flash pasteurizer" found in so many commercial creameries. We finally devised a miniature "flash pasteurizer" with which it is possible to control the time

required to bring the cream to the pasteurizing temperature.

Before making any experimental studies with this laboratory pasteurizer, the entire assembly was first carefully cleaned and then sterilized under steam pressure, to preclude the possibilities of any outside contaminating influences. After such preliminary precautions, the apparatus was set in motion to heat successive portions of the same raw cream (previously neutralized) to a series of different temperatures, starting with the highest temperature to be studied as the first in any series. When the temperature and time conditions were properly regulated the laboratory equipment was operated for 5 minutes at the highest temperature to be studied before any samples were taken. Inasmuch as the capacity of our laboratory flash pasteurizer was operated at the rate of 60 cc. per minute (1 cc. per second), we found it convenient to take small samples for our studies of bacterial destruction. Incidentally, in all experiments outlined, 30 seconds were required to heat the cream from approximately 100° F., to the various temperatures studied. In taking the bacteriological samples, 2 or 3 cc. constituted our sample, which was taken at the outlet. Inasmuch as the samples were taken at the outlet, no appreciable holding period was involved, for the instant the heated cream left the outlet and came in contact with the glass side of the sample jar, the cream was pre-cooled, inasmuch as the sample jar was thus collected (generally 2 to 3 cc. in as many seconds), 1 cc. of the sample was immediately transferred to a sterile water blank for dilution purposes, which provided further cooling, as the sterile water was also at room temperature (70° F.). The combined operations of sampling and preparing a dilution of the sample consumed from 10 to 15 seconds.

When the cream pasteurized at the

highest temperature had thus been sampled, the pasteurizer was adjusted to operate at the next lower temperature and then, after an additional minute's operation (to permit the thorough flushing of any hotter cream), the next sample was taken, repeating the process until the series being studied was completed. This raw cream was then sampled and all samples were plated immediately—within 30 to 45 minutes of the time the experiment was started.

In our preliminary work we made studies upon the destruction of bacteria in six different experiments upon six different batches of raw neutralized cream. We examined the samples for the standard plate count, using standard nutrient agar, and for yeast and mold colonies, using potato dextrose agar. The temperatures studied were 165°, 170°, 175°, 180°, 185°, 190°, and 195° F. In only two of the six experiments did yeasts and molds survive pasteurization, and in both instances only at 165° F. The pasteurization efficiencies in all six ex-

Blank					—	—	0.7

(—) denotes less than 1 per cc. in microbiological examinations

periments exceeded 99 per cent as measured by the standard plate count for all the temperatures studied.

In order to give you a picture of what the bacterial survivals were, we have compiled a curve in Figure 2, representing the logarithms of the average counts for each temperature, while the logarithms of the actual counts themselves are plotted. It was necessary to use the logarithms in order to illustrate adequately the bacterial survivals. In referring to the graph, it is obvious from the slope of the curve that considerable differences in the survival of bacteria were obtained in comparing 165°, 170°, 175°, and 180° F., with each other. Above 180° F., and particularly above 185° F., it is obvious that the differences in bacterial survival became less marked; in fact, the average standard plate counts of the different creams pasteurized at 180°, 185°, 190°, and 195° F., averaged 3,000, 2,330, 2,000, and 2,000 per cc. respectively.

In another series of studies, we have applied to cream samples "flash" pasteurized at 160°, 170°, 175°, 180°, 185°, and 190° F., a slightly modified form of the short method of Scharer and the 2½, 8, and 24 hour incubation technics of Kay and Graham using the Lovibond tintometer for measuring the color production by indophenol. In

Table I are given these data as well as the yeast and mold counts obtained with 5 days' incubation at 21° C. using potato dextrose agar, the coliform bacteria counts obtained in 18–24 hours at 37° C. using violet red bile agar and the standard plate counts obtained with 48 hours' incubation at 31½° C. of the differently treated samples. Incidentally, in these experiments a period of approximately 30 seconds was used in bringing the temperature of the cream from approximately 90° F. to the "flashing" temperatures studied. The heated samples were maintained at the different temperatures for a period of 2 to 3 seconds and then cooled as rapidly as possible in a film similar to that condition encountered in the surface cooling of milk by cabinet coolers. As soon as the samples were cooled, they were plated for the different microbiological examinations, following which they were prepared for the different phosphatase tests as outlined. Sour cream which previously had been adjusted to an acidity of 0.23 per cent (as lactic acid) was used for this experiment. All equipment used in these cream studies was previously sterilized by autoclaving at 15 lbs. pressure for 30 minutes.

The data given in Table I are generally representative of the results obtained in similar experiments. We are

listing in Table II the range of the results obtained in applying the phosphatase tests to cream samples "flashed" pasteurized at the temperatures indicated. Such results were obtained from at least nine experimental trials as described above.

temperatures were maintained within the range of 181° F. to 183° F. we found the mixed cream constituting the complete run which had been so pasteurized, gave a negative reaction by the short method and phenol values of 2.2 Lovibond blue units for the 2½, 8,

TABLE II

Normal Range of Results Obtained in Applying Phosphatase Tests to Cream "Flashed" at 175, 180, and 185° F.

<i>"Flashing"</i> Temperatures Degrees F.	Short Method	Lovibond Blue Units		
		2½ Hrs.	8 Hrs.	24 Hrs.
175	Doubtful to Negative	3.0-3.2	2.9-3.0	3.0-3.1
180	Negative	2.1-2.3	2.0-2.2	2.6-2.9
185	Negative	1.9-2.3	2.0-2.1	2.3

From the data in Tables I and II it is evident that "flash" pasteurization at 185° F. for 2 to 3 seconds is adequate as indicated by the production of less than 2.3 Lovibond blue units in samples incubated 2½ hours or 8 hours and not more than 2.3 units in 24 hours.

In actual plant practice we have had the experience that cream presumably "flashed" at 180° F. gave a positive phosphatase reaction by the short method and Lovibond blue units of 4.4 at 2½ hours and 7.2 units at 8 hours. In checking the plant performance we discovered that the recording thermometer chart showed that the pasteurizing temperature of the cream had fallen below 180° F. for 2 or 3 minutes during the continuous operation. The record showed the lowest point to be 177° F. Although we found the instrument to check accurately with a certified thermometer, the possibility that the pasteurizing temperature may actually have fallen below 177° F. cannot be successfully eliminated inasmuch as the instrument involved did not exercise maximum sensitivity under the conditions of operation prevailing at that time. Later in subsequent trials in which the

and 24 hours incubation periods. These lower phenol values in the commercial samples are doubtlessly due to the fact that the "flashing" temperatures of 181°-183° F. were maintained for approximately 15 seconds. Repeated plant trials where temperatures of 185° F. or higher were used have consistently given similar results. In fact, where positive results have been obtained upon samples of cream by any of the methods mentioned we have found without exception that the pasteurization practice has been inadequate, due to faulty thermometers, the leaking of raw cream into the pasteurized cream or some similar defect.

In applying the short method to cream samples we have found the use of amyl alcohol an indispensable aid inasmuch as the failure to use the same markedly impairs the sensitivity of the test. We have also had the experience that doubtful or even negative interpretations have been applied which gave positive results when the blue color otherwise obscured was extracted by the addition of the alcohol.

In view of the fact that extensive use of butter cultures is made in an effort to impart or develop characteristic

flavor and aroma, we have made some studies of such cultures or starters to determine how they might influence the phosphatase test applied either directly or to cream inoculated with the same. On all samples of starters made from milk pasteurized at 180° F. for 1 hour, and irrespective of the acidity to which the culture was ripened, we have never obtained a positive test by the short method. The highest phenol value we have ever obtained on butter cultures prepared from milk pasteurized at 180° F. for 1 hour was 2.1 Lovibond blue units after 24 hours' incubation.

We have made some studies on cream "flash" pasteurized in the laboratory and also under commercial conditions. A quantity of cream "flashed" at 183° F. under commercial conditions and maintained at this temperature for approximately 15 seconds gave a negative reaction by the short method and phenol values of 2.2 Lovibond blue units with the 2½, 8, and 24 hour

incubations. The butter churned from such cream gave a negative reaction with the short method and phenol values of 1.6, 1.7, and 1.7 for the 2½, 8, and 24 hour incubation periods respectively. Inasmuch as this work was confined to only one trial further study of this point is necessary.

We have, however, made some laboratory studies upon the butter made directly from cream "flashed" at different temperatures similar to methods outlined in the cream experiments discussed above. The results of two of our experiments are shown in Table III.

The data in Table III tended to give further confirmation to the adequacy of 185° F. or higher as the proper temperature of "flashing" cream for creamery butter making. However, further work on the proper amount of butter serum to use is contemplated.

We have applied the short method to water supplies used for washing butter and also to butter salt with negative

results. The same was found to apply to both lime and soda neutralizers used for adjusting the acidity of sour cream. Chlorine solutions containing not more than 50 p.p.m. also gave negative results—in fact, the greatest phenol value obtained with 24 hours' incubation was 1.2 Lovibond units. All such samples tested were obtained from creameries operating in the States of Illinois, Indiana, Iowa, Missouri, Kansas, and Oklahoma.

We have had the experience that samples of butter giving a negative reaction with the short test when fresh would give a doubtful or a positive reaction after being held 8 days at 70° F. for the keeping quality test. In fact, over 90 per cent of our samples which entered the keeping quality test as negative have given a positive reaction upon completion of the keeping quality test. That phenol production in such samples might be attributed to bacterial activity appears to be indicated by the facts that, (1) sera from fresh butter samples which originally gave a negative reaction still give a negative result when two drops of chloroform per 0.5 cc. of serum was added and held for 8 days at 70° F. while the same sera to which no chloroform was added gave a positive reaction under similar conditions of holding, and (2) the same sera held 8 days at 42° F. without the addition of chloroform gave negative results for indophenol by the short method. Whereas butter is normally 30 days old before it reaches the consumer and, during the interim between its manufacture and its consumption, is subjected to a variety of temperature changes, it is desirable that more be known concerning its history before a positive phosphatase reaction can be definitely attributed to improper pasteurization of the cream from which the butter was made. Incidentally, we have had the experience of having butter which gave

a negative phosphatase reaction by the short method develop a definitely positive reaction after overnight storage in a refrigerator where a motor used for circulating brine developed a short circuit and, due to fuse failure to break the circuit, burnt the armature windings and charred the wooden wedges. The smoke which developed contaminated some of the exposed surfaces of butter which then gave a positive reaction. We are now investigating the possibility of similar reactions of butter stored under refrigeration with smoked meats or meats impregnated with smoked salt.

A chlorinated surface water supply in which the possibility of slight phenol production due to the oxidation of algae-growth giving to butter washed with the same a positive phosphatase test even though the cream used in its production is apparently adequately pasteurized, has just recently come to our attention. Unfortunately, we are unable at this time to give any definite information.

These different experiences and results obtained with the phosphatase test demonstrate clearly the desirability—in fact, the necessity of making check determinations for indophenol in order to preclude pseudo-phosphatase reactions.

We have used both the Kay and Graham reagents and methods in many of our determinations. The usual precautions of fresh reagents and clean glassware which had been washed with phenol-free detergents and then thoroughly dried before use have been meticulously observed. In using the short method of Harry Scharer,⁵ we have made certain modifications which appear to give us better end points with which we have been able to determine more accurately a positive or a negative result. We have increased the incubation time from 10 minutes at 100° F. to 15 minutes at 105° F. This added

time and temperature appears to give a better agreement when compared with the longer methods of Kay and Graham.¹ The addition of amyl alcohol apparently gives a better extraction of color with less difficulty of forming an emulsion which will not allow the color to rise to the surface of the sample.

In preparation of our butter samples we melt butter in a water bath at 45° C. for 20 minutes, allowing the sera to settle to the bottom of the conical centrifuge tube. A clean pipette is then used to withdraw 0.5 cc. of the sera and then transferred to the test tubes containing 5 cc. of the buffered substrate solution.

SUMMARY OF RESULTS

1. Our experiments upon sour cream adjusted to conventional churning acidities and "flashed" at different temperatures have indicated that 185° F. or higher will give negative phosphatase reactions upon samples treated by a modification of the Scharer short method as well as by the Kay and Graham 24 hour incubation method.

"Flashing" cream at 180° F., however, gave negative results by the modified Scharer short method as well as by the 2½ hour and 8 hour incubation methods of Kay and Graham, although doubtful results were obtained by using the 24 hour incubation period.

Cream "flashed" at 175° F. gave doubtful results by the modified Scharer short method and positive results with the Kay and Graham

methods whereas "flashing" below 175° F. gave positive results with all methods.

2. Butter freshly made from sour cream of adjusted acidity which had been "flashed" at 185° F. or higher gave negative phosphatase tests when using the modified Scharer short method and the Kay and Graham 24 hour technic.

3. Some indications of possible phenol production by bacterial activity in butter samples subjected to the keeping quality test of holding at 70° F. for 8 days (100 per cent humidity) have been observed.

4. Due to factors which may stimulate phenol production in butter subjected to normal changes in temperatures and environment during the interim between its manufacture and consumption, caution should be exercised in interpreting a positive phosphatase test as indicative of the inadequate pasteurization of the cream used in its manufacture.

5. Further work should be done to establish the equitable amount of sample of butter serum to be used to interpret its relation to the original cream from which the butter was made.

The New Appraisal Form for Local Health Work*

W. F. WALKER, DR.P.H., F.A.P.H.A.

*Director, Division of Health Studies, The Commonwealth Fund,
New York, N. Y.*

IT is indeed a pleasure to present the *Appraisal Form for Local Health Work* to the International Society of Medical Health Officers. Since 1924, when the first generally accepted schedule for appraising public health services was developed by Rankin, Crumbine, and others, the health officers of the country have been its severest but most constructive critics and therefore its strongest friends. They have contributed to its success and sound development by making available their personal experience and the collected records of their departments at times of revision. They have been quick to recognize advantages and equally quick to recognize and speak frankly of inconsistencies and shortcomings.

It has been my extreme good fortune to have the privilege of participating both in the development of the original tentative schedule in 1924 and the subsequent revisions, including the present one. Those of you who have sat around the discussion table when revisions were in progress will, I am sure, agree that those occasions are practically a complete course in public health administration. To have present-day health practice in the various fields

of public health service discussed by such people as Winslow, Chapin, Godfrey, Freeman, Ruhland, Waller, Leathers, Whitaker, Bishop, Fleming, and Sippy, is stimulating. It is invaluable, however, in developing a practical measuring rod for public health services, to have the discussion of these practices which comes by letter, by personal contact, and otherwise from city and county health officers all over the country as they use the various editions, or attempt to apply them to their own programs.

In keeping with the Association's policy over the years, of seeking the aid of health officers in the field in the revisions of the *Appraisal Form*, the specific advice of about 50 health officers who had used the Form was sought with regard to a half dozen questions of policy in this revision. The opinion of this group was that:

1. The *Appraisal Form* should be a convenient guide to health workers in the development of a program.
2. The standards set up should represent the optimum range of practice throughout the country.
3. The revised Form should not be less inclusive than its predecessors.
4. With all its faults, score was an essential element if the Form were to continue to be as useful as all testified it had been.

With these general sailing orders, the committee set to work with the

* Read before the International Society of Medical Health Officers in Kansas City, Mo., October 24, 1938.

10					

namely, that all parts of the public health program must be considered from the viewpoint of the administrator—the health officer—rather than from the point of view of the specialist, such as a director of a particular service, and, though the committee has continuously sought the advice and assistance of the special groups—laboratory, sanitation, vital statistics, epidemiology, child hygiene—it has tried to maintain a proper balance of emphasis which at times has not been easy.

THE NEW FORM

The present Form consists of three main parts. Part I, General Information, has been greatly enlarged in this

issue to provide a place for recording pertinent facts in some detail regarding administrative organization of health services, finances, economic status, the racial and age distribution of population, vital statistics relating to births and to deaths from certain causes, hospital and medical facilities, public health personnel.

Part II, is a detailed schedule for surveying and appraising selected health activities which are believed to be indicative of the community service.

In Part III, Selected Health Indices, the most objective and significant items from sections I and II are brought together for easy review.

To give a better idea of material

contained in these sections, I should like to present a few specimen items. From Part I, I have selected the table showing hospital facilities (1) and medical personnel (2) (see Figure I), as illustrative of the type of information which one should have about a community as a preliminary to appraising its health services.

I must present a number of sample sections from Part II in order to illustrate the various types of change made in this revision.

VARIABLE BASE

Figure II illustrates the most far reaching change which has been made in the *Appraisal Form*, namely, the variable base for scoring. To avoid the obvious error, which has been frequently criticised in the past, of making a service a requirement where no service is necessary because of the nature of the problem, scoring in this edition is on a variable base. The first two items under diphtheria control shown in this table clearly cannot be carried out unless diphtheria is present and these items, as the note indicates, may be omitted from scoring in an area where no diphtheria is present in the year under consideration. The third item, however, I am sure you will all agree, is at present universally applicable and all communities may well be rated on the percentage of the population under 5 years who have been immunized.

In Figure III, a similar example of this principle in another field is shown in obstetrical nursing service. Here the determination of whether the service should be scored on or not in a particular area depends upon the demand for this type of service, it being the opinion of the committee and its consultants that unless there are 100 women delivered at home each year it is questionable whether such a service can be economically offered by a health

department. This item also illustrates another point, namely, that the *Appraisal Form* is attempting to keep pace with changing practices in public health work. The percentage of the deliveries for which nursing assistance is expected has been raised from 5 to 25.

Figure IV illustrates a different kind of variability and is drawn from the section on water supply. Here the item with the dagger applies only to rural areas and is omitted from consideration when the Form is applied to cities, and items c and d, dealing with industrial water supplies, are taken into consideration only in urban areas. Item a, which is not shown, rates the percentage of urban population served with a public water supply.

Such changes as these make the Form much more specific for the community under consideration and while it throws out any possibility of direct comparison of scores between communities, it does not vitiate comparison of scores of the same community from year to year as the variation in scoring base is simply a reflection of the changing health problems.

QUALITATIVE CRITERIA

Probably the criticism of the Form most frequently made was that it did not give sufficient consideration to the quality of service rendered but scored entirely upon quantity performance. The committee has sought to include qualitative standards wherever possible. One difficulty confronted in this attempt was that there are so few fields in which acceptable standards of quality have been developed. Another point which must be borne in mind is that though services are expressed in quantitative terms, the summation of these may truly reflect the quality.

As examples of such changes, may I cite the criteria set up for judging the typhoid fever control services as shown

FIGURE IV

in Figure V. The first three of these are definitely indications of quality of the service. To be sure in appraising an area, one must be certain that the practice is consistent in the handling of all cases. This may mean spending time in the field with the individual who is responsible for this activity.

Figure VI is an example of the inclusion in the *Appraisal Form* of definite standards which have already been set up by recognized leaders. In

this instance the criterion of minimum satisfactory treatment of syphilis as established by the Coöperative Clinical Group is incorporated as a scoring item.

The criteria set up for judging institutional care of tuberculous cases are examples of the possibility of judging quality through the application of quantitative criteria. These criteria are shown in Figure VII. Early editions of the Form were content to judge the adequacy of institutional

care of tuberculosis simply on the number of patient days per death. Each revision has added to this, first emphasizing minimal cases, and, in this revision, attention is also directed to the use of collapse therapy, the prompt hospitalization of cases, and the continuity of treatment.

The organized medical service for maternity supervision is judged by the percentage of total cases under super-

vision and, as shown in Figure VIII, the average number of visits per case, the extent to which Wassermanns are made as a routine procedure, and the treatment of women with positive reactions. While there are other items that might equally well be selected as criteria of quality in this field, services meeting these requirements will almost without exception be carrying on a good program.

INDICES

The third section of the *Appraisal Form* is definitely experimental. Platt in an analysis of the *Appraisal Form* in 1927 pointed out that rating a community on a few typical items gave results which compared favorably with

the use of the larger Form. It proved that certain items had definite value as indices of the character of a community health service. Recently there has been a demand for a broader point of view in the formation of public health programs. It is now recognized

as desirable and necessary to consider composition and economic status of the population, the availability of health promoting facilities as well as the character of local health problems in program planning. In order to bring together certain items from which we may select reliable indices of these various factors when a sufficient volume of experience has been accumulated a tentative list of such items is included as Part III of the new Form (Figure IX). Out of such accumulated material we may eventually be able to discover some consistent relationship between economic and environmental factors, health status, and health practices. Only general use and time will tell whether this is a wise extension of the *Appraisal Form* or not.

USES OF THE APPRAISAL FORM

One of the most significant changes in the *Appraisal Form* over the past 14 years of its existence is the change in use. As originally designed it was primarily to serve as a rating schedule in order that city and rural health programs might be graded according to accepted standards of practice. Early editions carried little explanatory material which would indicate why criteria were selected or the basis for standards set up. In fact, the first draft of the City Appraisal Form did not even include a survey schedule. Experience soon indicated that the survey is the most useful phase of an appraisal and that the scoring is simply a convenient method of expressing the findings as they relate to the various phases of the service or the program as a whole. The Form was being used by many health officers as a guide to administrative practice. So, with this edition, this phase has been emphasized and strengthened by inserting brief statements throughout the schedule indicating the philosophy which the com-

mittee believes underlies certain services. In several states, aid from the state department is available to local health officers in making periodic appraisals. This has the obvious advantage of giving the health officer another pair of hands to assist in the collection of material and of providing a person with a disinterested point of view, which is always helpful in interpreting the findings of such a study.

With the introduction of the variable base for scoring, the Form becomes in fact primarily a manual of practice, chiefly useful to the administrator in studying the community needs, the function of his department with regard to a particular service, and this trend of development from year to year.

With the introduction of the selected list of health indices, a new instrument is suggested for brief, readily made summaries of the health conditions and needs, and of community characteristics bearing on these conditions and needs. Local health officers may find these indices, or a part of them at least, useful for periodic surveys and comparison. State health officers may find the indices of value to summarize and compare conditions among local areas or to follow trends for periods of time. Here is an experimental tool which may prove especially useful when detailed appraisals are unnecessary or impracticable.

In conclusion, may I reiterate that the Committee on the Appraisal of Local Health Work feels very deeply indebted to the health officers for continued assistance in the development of this document. It is your Form; its primary function is to aid you; without your use of it, your criticisms, and your help, it could not exist. It must keep pace with changing conditions and practices, and we continue to stand ready to serve you in keeping it up to date and as useful as possible.

Practical Methods for the Control of Hygienic Exposures*

G. A. COBURN

Personnel Director, Delco-Remy Division, General Motors Corporation, Anderson, Ind.

FOR the successful solution of any task or problem, certain information and knowledge is necessary. Certain tools and equipment are needed and quite often a certain amount of skill and technic comes in handy.

In launching a campaign for the control of industrial exposures, there are some prerequisites which are necessary for success and others which are highly desirable.

1. One of the first things to know is what exposures exist in your plants, what is the nature and extent of the exposure, what has been done to control them, how successful is this control. In short, a complete survey of the plant is necessary.

The use of the following headings is suggested for the form used in making this survey:

1. Department name and number
2. List of hazardous operations in the department
3. Nature of exposure in each hazardous operation
4. Number of workers exposed
5. Method of control in use
6. Effectiveness of this control
 - a. Based on health study of those exposed
 - b. Based on air analysis, etc.
7. Recommendations for improvement

Such a survey as this not only gives one a complete picture of the condition of your plant, but helps in determining the points against which your control campaign should be directed. It can also serve as a record.

2. The second necessary item is a physician or medical department that has specific knowledge of the hazardousness of various toxic substances, dusts, etc., from a health standpoint and that also has knowledge of the extent to which these exposures have affected and are affecting the health of the workers.

3. The third prerequisite is a plant engineering force that is interested in the problem and is well versed in the design, installation, and maintenance of hoods, exhaust systems, and other control mechanisms.

4. Another desirable factor is an interested, well informed, and coöperative plant supervisory force.

5. A fifth item which is desirable but not absolutely essential, is the necessary equipment for air sampling to determine dust concentration and air contamination. Such equipment is helpful in determining whether control is necessary and in checking the effectiveness of control used.

6. In view of the fact that the study and control of industrial exposures is of recent growth, it is often desirable to have one individual charged with

* Read at a Joint Session of the Industrial Hygiene and Public Health Nursing Sections of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 28, 1938.

this responsibility. He should be able to coördinate the efforts of the existing medical, engineering, and plant supervisory forces.

GENERAL METHODS OF CONTROL

The overall objective is, of course, to remove all exposures, or, failing in this, to limit exposures to the point where there is no danger, *i.e.*, sub-threshold exposures.

Following is a list of the methods of control generally used in industry to accomplish these objectives:

1. Substitution of a safe material for the one causing the exposure, as the use of less toxic solvents for benzol and the use of steel shot for sand in cleaning.

2. Substitution of a safer process for the one causing the trouble, such as wet grinding and drilling for dry grinding and drilling and the use of a wet process in making and handling plates for storage batteries.

3. By preventing the escape of toxic substances and harmful dusts into the air which is used by the workers.

This is accomplished in two ways: first, by making the operation entirely automatic, thus eliminating the worker and then enclosing the equipment so as to prevent the escape of harmful substances. Examples of this method are automatic sand blasters and painting by conveyor dipping or automatically controlled spray guns. Second, by power exhaust ventilation. This method is the most practical and most generally used for the removal of gases, fumes and dust when a worker is essential for the operation. A suitably designed hood is placed close to the source of the trouble, and a suction fan draws the polluted air away to either the outside or to a filtering plant or dust collector.

4. By the use of protective equipment by the worker, such as goggles for eye protection from glare or flying

particles, rubber gloves, boots or aprons from acids, oils, solvents, etc., respirators against dust, and gas masks against toxic gases and fumes.

5. By the exercise of proper hygienic care on the part of the worker—proper washing and bathing by those who work in oil, and observing certain health rules by lead workers.

6. By lowering the exposure. This is accomplished by the rotation of workers to less hazardous jobs or by shortening the working hours.

7. By selecting employees for hazardous exposures who are the least susceptible to those exposures. Those who are to be subjected to exposures from dust, fumes, and gases should be free from respiratory difficulties. Lead workers should be free from previous exposures and from ailments of the alimentary tract. Those who are to work in oils, paints, etc. should be free from skin disorders.

PRACTICAL METHODS OF CONTROLLING CERTAIN EXPOSURES

DUSTS

In general there are two classes of dust to be considered:

1. Those capable of producing respiratory troubles, such as fibrosis of the lungs.

2. Those that may cause systematic poisoning, such as lead compounds, etc.

In those industries where many of their products are shaped from cast iron (as is the case with Delco-Remy) the problem of exposures from the dust created by the machining of cast iron, is an important one. While Dr. Sampson, in his recent study of iron ore mining, is of the opinion that ferrous oxide dust is not conducive to tuberculosis, one has in cast iron machining, mixed with the iron dust, considerable silica dust which comes from the sand used in coring and molding. And, of course, with silica there is the danger

of silicosis with its attendant tuberculosis.

Previous to 1934, very little effort had been made by our company in controlling the dust hazard in our cast iron machining departments and as a result work in these departments was considered a dirty job. The workers were convinced, and possibly logically so, that any respiratory difficulties which they had were either caused by or aggravated by the dust to which their work subjected them. Labor turnover was relatively high. Sufficient data are not available to determine whether there was any increase in the tuberculosis rate. The tendency to such an increase was offset by our practice of transferring men "out" of the department to other lines of work based upon the recommendations of the medical department.

During the summer of 1934, the Metropolitan Life Insurance Company made a rather extensive survey of our plants. As a result of this and subsequent surveys by that company and by ourselves, an extensive campaign of dust control has been carried out. On the original survey before any control methods were in use, the dust concentration in our cast iron machining departments ranged from 5 to as high as 12 and 15 million particles per cubic foot of air. Since the installation of exhaust systems, these counts are now as low as 1 million and seldom in excess of $2\frac{1}{2}$ million particles per cubic foot of air. The jobs are now relatively clean and there is little or no complaint on the part of the workers. In fact, these departments are considered very satisfactory places in which to work, and the requests for "transfers out" are few.

The most practical way for removing dust is to place a suitably designed hood around the source of the dust and by a suction fan to draw the dust laden air to either the outside or to a dust

collector or filtering system. In view of the fact that the installations of exhaust systems vary considerably with the different types of machines, they are difficult of description.

In general, in the design and installation of exhaust systems, several points should be kept in mind, namely:

1. A given velocity of air is required to carry dusts of a given density—4,000 feet per minute is recommended for most dusts, 5,000 for lead and 2,500 to 3,000 feet per minute for gas, fumes, smoke, etc.

2. That the area of the hood opening must be kept in such a proportion to the area of the pipe carrying the air away from the hood that the velocity of the air in the opening does not fall below the velocity required for moving the dust.

3. The design of the hood is of great importance as the efficiency varies decidedly with different hoods. Also the hood surrounding the source of dust must be so designed and shaped that it will not slow up or hinder the loading or unloading of the fixture on the part of the operator. Otherwise his tendency is to disregard the use of it.

4. The question of heat loss in cold weather must be considered if the dust laden air is to be discharged to the outside. Such a consideration may make it advisable to run the air through a filtering device and then back to the plant.

Occasionally, due to the possible short life of the product or of the particular method of machining in use, the outlay for an exhaust system is inadvisable from a financial point of view. In one such case in machining cast iron, the dust count was reduced from around 15 million to well below 5 million particles per cubic foot of air by the simple expedient of removing all air hose and substituting brushes for cleaning off fixtures and by having the floor swept up after the regular force

had gone home from the shift. If at all possible, holding fixtures should be so designed as to permit the chips and dust to fall free and thus do away with the necessity of blowing them off with air, which increases the dust in the air considerably.

The engineer engaged in designing and installing exhaust systems, having, as he does, a type of mind which demands exactness, would be pleased if he had a definite figure for permissible dustiness. In this regard Drinker states that "the point has not been reached where a manufacturer can be told with certainty that his plant will have no silicosis if he keeps dustiness down to some definite figure."

The varying susceptibility of the employee, the period of exposure, the type of dust, the amount of free silica, the lack of uniformity in concentration are factors which make it difficult to set a figure of permissibility, and one might also add, the lack of definite data.

In the South African gold mines where the dust is said to contain more than 85 per cent free silica, a tentative standard of 8.5 million particles per cubic foot has been set as the upper limit of dustiness allowable.

From the results of a study made by the Public Health Service in the granite cutting industries it was found practicable to suggest a tentative standard for the upper limit of allowable dustiness between 10 and 20 million particles per cubic foot of air for workers exposed to dust resulting from granite cutting. The same limit would presumably be applicable in the case of other dusts of the same physical characteristics, particularly with a silica content of 35 per cent.

The Industrial Commission of Wisconsin reports as follows:

The maximum silica-dust concentration considered permissible in the air breathed by a workman at any point in the normal breathing zone has not been definitely estab-

lished. The commission, its advisory committee, employers, and scientists have agreed on a tentative figure of 15 million countable dust particles under 10 microns in longest dimension with free silica content of 35 per cent in a cubic foot of air as determined by U. S. Public Health Service technic. Variations in free-silica content will make proportional inverse changes in this standard. In the case of practically pure silica the permissible dust count would be 5,250,000 countable particles.

More recently other states have established a standard of permissibility in the neighborhood of 10 million. Therefore, in order to give our plant engineering staff a goal toward which to work our company has set up empirically a figure of 5 million particles per cubic foot as being the high range of permissibility. In view of the fact that all of our castings are made from permanent iron mould, and the only source of sand is from the sand cores, it is felt that this figure of 5 million is well on the safe side.

The discussion up to this point has had to do with dusts containing silica. In an average manufacturing plant there are usually a number of other dusts present which are not particularly harmful in that they are not fibrosis producing. However, in view of the fact that dust of any kind is disagreeable and that the average worker feels that "dust is dust," and that any respiratory irritation which he may experience is due to the dust, and since the average practising family physician will usually concur with him in his belief, our company has adopted the policy of controlling all dusts regardless of their nature.

PLATING HAZARDS

Several years ago, our company experienced considerable health difficulties in our plating, particularly chrome plating. Due to the extreme heaviness of chrome fumes the usual method of exhaust ventilation was inadequate. Our troubles continued until new

chrome plating equipment was purchased wherein the control of fumes was an integral part of the equipment. By the present method, the heavy chrome fumes are pulled downward by suction through openings at the edges of the tank, to a container underneath, where a large portion condenses. This air is then drawn through a vertical duct to a cylinder of approximately twice the diameter of the duct. This cylinder has a series of baffles which, assisted by the lowered velocity, entraps the remaining chrome and it is washed back to the container underneath the tank by a small stream of water. This chrome solution which thus collects is added to the original chrome tank.

With this new system, the air shows no trace of chrome and our health difficulties have vanished.

In zinc, copper, cadmium, and nickel plating, theoretically at least, no gases other than oxygen and hydrogen are given off. Actually, as the plating is speeded up, the plating solution becomes heated and some of the solution is carried off with the oxygen and hydrogen in the form of a mist. Thus with the advent of faster and more up to date plating methods, it has been necessary to cover the tanks and provide forced exhaust ventilation.

LEAD

For 10 years, our company has been engaged in the manufacture of storage batteries. No serious cases of lead poisoning have occurred and only occasionally has an employee had a slight touch of it. In general our method of control is as follows:

1. Employ only those people who have been free from lead exposure in the past and only those who are free from ailments of the digestive organs.
2. Isolate all operations which may give off lead dust from those that do not.
3. Keep the floors, paste machines,

conveyors, and pasted plates wet at all times to prevent the giving off of dust.

4. Make regular analysis of the air for lead at the strategic points of exposure and endeavor by means of exhaust controls to hold the lead content of the air down to a safe point.

5. Physical examination of all lead exposed employees once a month, and at the slightest indication of lead intoxication, transfer the worker to a job with little or no exposure.

6. Require the worker to wear a respirator in those few places where the lead concentration is above a safe point.

7. Insist on personal cleanliness and hygiene on the part of the worker.

SOLDERING

Throughout our plants, there are soldering operations which are done by machine, by dipping or by an electric solder iron. Most of these operations are provided with exhaust ventilators, not so much to prevent lead absorption, as to remove the smoke incident to the burning of the flux and insulation on the parts being soldered.

BAKELITE

In our bakelite department, the bakelite power is formed into a pill of appropriate size and shape for use in molding.

These pill machines are entirely enclosed in a small room which is provided with exhaust ventilation.

OILS

The control of skin disorders of employees working in oils has always been a difficult problem.

Many different approaches have been made by different concerns. Our company has tried a variety of measures. Our method of approach at present is as follows:

1. A central supply system from which oil is supplied to all plants. This system has a storage tank for new oil

and a settling and filtering set-up for used oil.

2. Use of a protective hand ointment.

3. Program of cleanliness with proper wash room facilities provided.

4. Discontinue the use of kerosene and gasoline for washing hands and use a mineral seal oil instead.

With 400 operators working in oil, there has been only one minor case of so-called oil poisoning in the past 2 years. It is our belief that personal

cleanliness is the greatest factor in control.

This completes the list of hygienic hazards with which our company has had to deal. I realize that many of you have numerous other hazards that I have not discussed, because we have had no experience with them.

I believe any company, with a certain amount of determination, plus reasonable intelligence, can successfully control its plant hazards.

DISCUSSION

ASSEMBLED BY CHARLES L. POOL, F.A.P.H.A.

Chief Engineer, Division of Industrial Hygiene, State Department of Public Health, Providence, R. I.

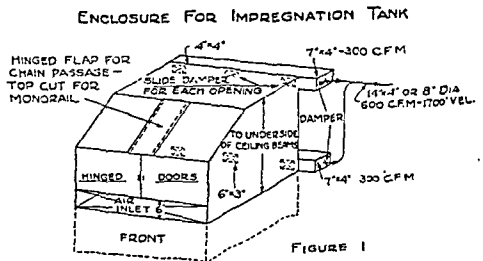

MR. COBURN has outlined the methods available for controlling hygienic exposures and has shown how good engineering practice is able to surpass the physiological dicta in vogue. In order that a prepared discussion might have working value industrial hygienists were asked to submit practical examples in condensed form.

Reduction of Benzol-Toluol Vapors—Gray¹ arranged for Postman² to contribute data on their bureau's study leading to correction of exposures to benzol and toluol vapors from impregnation of clutch disks. The Connecticut Department of Health Sanitary Code stipulates maximum concentrations of 100 p.p.m. for benzol and 200 p.p.m. for toluol.

Six minute runs during insertion and removal of disks from an impregnating tank exposed the operator to an average of 350 p.p.m. (490 p.p.m. when a nearby window was opened) of toluol, causing watering of eyes at peak concentrations, and similarly, to 520 p.p.m. of benzol (21 min. run). Twenty minute samples of (a) aisle air between drying ovens showed 920 p.p.m. of

toluol and (b) breathing level near drying racks, 480 p.p.m. Through a 7 minute period during removal of disks from drying oven the activated charcoal determination showed an exposure to 150 p.p.m. of toluol (but results may be too low at the high temperatures).

Recommendations included sketches

B—Single Exhaust Connection

and outline of designs for control of vapors at points of generation. Fig. 1 outlines an enclosure for impregnating tanks, and Fig. 2 a ventilated chamber for temporary safe storage of treated disks between operations. Fig. 3 shows an interior view of the enclosure in place over an impregnating tank. An enclosure outlined for the floor pressing operation was about 25' long, 18" wide and 30" high, with a dampered opening to each of 16 pressing stations (60 c.f.m. for each). Hinged doors open up each pair of stations. Ducts 8" by 5" convey vapors to a fan suction (10" dia., 750' vel., 950 c.f.m.).

Suggestions included means for achieving results without hampering the operations, for conserving vapors by double walled tank enclosures, or water-jacketing of exhaust lines where the solvent (toluol) is used hot, dampers for conserving vapors when the en-

closures are in place, leak-proofing of dryer housings with maintenance of slight suction, handling of solvents and solutions by pipe line to eliminate addition to tanks from open buckets, stirring with paddles, and emptying by ladles, and use of canister type respirators for the irreducible occasional exposures, e.g., during removal of racks of disks from tanks, and transfer to floor pressing operation.

Determinations of resulting exposures are planned. The installation did not follow the outline in every detail but results are obviously satisfactory.

Isolation of Dusty Process—Lamenzo³ described an ingenious application of engineering to accomplish inexpensively an improvement in dust control which first looked costly. In making clutch facings, asbestos was loaded into beaters and wet down. From several possible solutions, the insurance carrier recommended to the manufacturer that loading from the beater floor be changed to loading through a chute from a ventilated enclosure placed on the floor above (see Fig. 4).

Asbestos dust on the beater floor was

Dust Concentrations—Millions of Particles per Cu. Ft. of Air	
Dust collector not operating	86.4
Dust collector operating	2.1

Visual inspection of the pictures taken of the weighing operation with and without the use of the exhaust system also show a striking difference in the dustiness of the air.

See Fig. 7 (Companion photo, in which no dust is seen, is not shown).

Design Fundamentals for Movable Hoods—Bowditch⁶ made available data sheets prepared by Hemeon⁷ from studies of their bureau to outline for industries a practical solution of stone cutting hazards. These were condensed:

Essentials of Banker Exhaust Ventilation: A suction device for each banker to keep the quantity of granite dust below 10 million particles per cu. ft. of air. For suction devices with hand pneumatic tools independent of and outside of the exhaust hood, an air velocity of at least 200 f.p.m. at a point 7" from center of face of hood resting on face of the stone; 6" when hood is hung unobstructed. Hood easily movable and kept within 6" of point of tool.

Recommendations: I. *Air Volumes, Plain Unobstructed Hood*—Withdraw not less than 540 c.f.m.

II. *Air Volumes, Flanged Hood*—Withdraw not less than 400 c.f.m. Flange may be metal, rubber, etc., approximately 3" wide and attached to the two sides and top of the hood which rests on the stone to be cut. Hood efficiency may be increased by the attachment, by a removable pin, of a device to encircle the cutting end of the 4-point chisel.

III. *Duct Construction*—Duct work laid out with fan near middle to exhaust nearly equal number of units from each side. Branch ducts connected to main at angle not greater than 45° and close to the large end of a tapered section. Ducts not to

FIG. 7—Weighing Operation. Exhaust System Not in Use.

extend into main. Elbows formed of not less than 5 sections for 5" ducts and 7 sections for larger ducts, with long curve. (The radius of curvature of center line of elbow at least 1½ times diameter.) Enlargements on a gradual taper. Clean-outs for ready cleaning of ducts; e.g., bends, junctions, dead-ends, foot of risers. Dusty air disposed of without recontamination of atmosphere.

IV. *Fan Size*—Determined by diameter of main through which air from all branches flows. Usually of such size that its inlet is not smaller than the main connected.

V. *Fan Speed*—Having fixed fan's inlet diameter, find at what speed it should operate from manufacturer's specifications—(a) capacity desired in terms of total c.f.m., (b) suction necessary at fan.

a. *Capacity of Fan*—Insure that the units at the end of the system get their full quota of air. Units near the fan draw more than those at the end, without balanced flow. Allow for a fan capacity greater than 400 c.f.m. per banker. Allowances estimated for layouts in supplement hereto given for installations of various sizes.

b. *Suction at Fan*—Depends mainly on loss through flexible suction device.

BANKER DUST EXHAUST SYSTEM
 TYPICAL PIPING LAYOUT FOR RUEMELIN UNIT
 (AND FOR C. F. BERG UNIT, FIGURES IN BRACKETS)

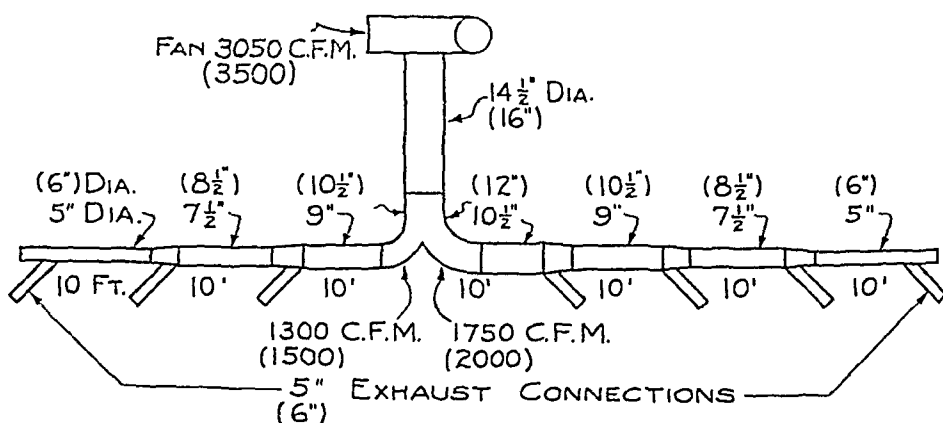

FIGURE 8

AFTER SKETCH BY
 MASS. DEPT. OF LABOR & INDUSTRIES
 DIVISION OF OCCUPATIONAL HYGIENE

Varies with type. See supplement.

VI. *Motor*—Size depends on fan capacity, desired suction, and fan efficiency. See supplement. Fan driven by motor through belt drive, rather than by direct connection for small speed adjustments for efficiency by changes in pulley size.

Maintenance—Performance of each unit checked by U-tube at least once a month. Cause of any drop in efficiency exceeding 10 per cent remedied.

Supplement is a guide only. Note the limitations stated. If layout requires departure from the essentials, figures given should not be used. No one type of unit is favored above another.

Supplement—The Ruemelin (or the C. F. Berg) Banker Exhaust Unit. Note: Values for C. F. Berg unit given in brackets.

Duct Sizes—When using flanged hoods with the Ruemelin (or C. F. Berg) Banker Exhaust Unit and minimum air volumes indicated, duct sizes

listed in Table I and Fig. 8 are advised. Where 5" (6") ducts from each of two banker exhausts join, increase the duct size by taper to a 7.5" (8.5") dia. Where a third 5" (6") exhaust duct joins the 7.5" (8.5") duct, increase the size to 9" (10.5") and so on as in table. Sizes larger than listed may result in deposits in ducts. Sizes smaller require excess power. Use larger sizes when air volumes are greater than the minimum specified.

Suction at Fan—The Ruemelin (C. F. Berg) Banker Exhaust Unit has an inside hose diameter of 4" (4.75") (C. F. Berg duct slides vertically inside a 5" duct and the connection after the chip trap is 6" in dia.) The Ruemelin connection to branch pipes is 5" in dia. To exhaust 400 c.f.m. through this device with a flanged hood, maintain a suction after the trap, as measured by a U-tube, of 3.6" (2.3") of water (and 470 c.f.m. for the C. F. Berg unit, to cover leakage). In general, necessary "fan static pres-

sure" will vary from 4" (2") to 6.5" (3"), depending on size of installation and arrangement of ducts.

Hood Characteristics—Check performance by static suction measurements at the hood, taken from at least 4 holes, beyond hood elbow and just before ball joint (10" to 12" above hood elbow), using a minimum air flow of 400 c.f.m., a suction at hood of 2.6" (0.8"), and hood coefficient of 0.93 if with flange; use 540 c.f.m., 6.7" (2.0"), and 0.78, respectively, if without flange. If suction is between 3.7" (1.1") and 6.7" (2") without flange, system may be made to conform by attaching flange.

Motor Size—Depends on number of bankers, suction loss, and fan efficiency. Estimated sizes for systems of various numbers of bankers up to ten are tabu-

tively insoluble, such methods of house-keeping as vacuum cleaning in the "Dipping Room," and mechanized application of glaze.

A typical glaze formula shows 61 per cent silica and 11 per cent lead oxide. It is becoming more common to fuse some constituents of glaze into "frit" to add in ground-up form to the glaze. This renders the lead difficultly soluble. The frit (perhaps 31 per cent flint) may constitute a third of the glaze. A typical glaze showed 28.5 per cent white lead. A wet ball mill produces from the constituents a fluid into which ware is hand dipped, dried, and handled before firing. Exposures are being reduced still more recently by glazing with the aid of automatic equipment in mechanically exhausted booths. These machines

TABLE I

Number of Bankers	Approx. Min. Fan Capacity (c.f.m.)		Duct. Dia. and Min. Fan Inlet Dia. (In.)		Approx. Min. Size Motor	
	Ruemelin	(C. F. Berg)	Ruemelin	(C. F. Berg)	Ruemelin	(C. F. Berg)
1	400	(470)	5	(6)	0.75	(0.5)
2	850	(970)	7.5	(8.5)	2	(1)
3	1,300	(1,500)	9	(10.5)	2	(2)
4	1,750	(2,000)	10.5	(12)	3	(2)
5	2,200	(2,600)	12	(13.5)	5	(3)
6	2,700	(3,100)	13	(15)	5	(3)
7	3,200	(3,700)	14.5	(16)	7.5	(5)
8	3,700	(4,300)	15.5	(17)	7.5	(5)
9	4,200	(4,900)	16.5	(18)	10	(5)
10	4,700	(5,500)	17.5	(19)	10	(7.5)

lated for bankers not much over 10' apart and no long ducts, particularly in the 5" (6") and 7.5" (8.5") sizes.

Economic Recovery of Pottery Glazes with Reduction of Dust—Rothmann⁸ furnished an illustration of control measures which pay in recovery of material and in reduction in severity of exposures in the pottery industry.⁸ Exposures to lead in the manufacturing of vitreous dinnerware has been lessened in recent years by improved housing, air sanitation, use of fritted glazes wherein the lead used is rendered rela-

tively insoluble, such methods of house-keeping as vacuum cleaning in the "Dipping Room," and mechanized application of glaze.

ture" will vary from 4" (2") to 6.5" (3"), depending on size of installation and arrangement of ducts.

These machines

8,500 lbs., occupied 1,445 cu. ft., had a free cloth area of 1,920 sq. ft., required a 7.5 H.P. motor, static pressure 5.4" water, velocity pressure 1.2" water, air 4,200 c.f.m., spray booth openings (both booths) 10.5 sq. ft., 400 f.p.m. air velocity at opening. Glaze recovered, 7.0 lbs. per hr., would be worth about \$610 per year if unit ran 40 hrs. per week.

Seven to 12 dust samples for each of three conditions of glazing showed for hand dipping, no ventilation, 7.4 million particles per c.f., ave., and 35.0 max.; for spraying without exhaust ventilation 28.3 m.p.p. c.f., ave., and 107 max.; for spraying with exhaust ventilation 3.5 m.p., ave., and 7.1 max. A run to show efficiency of collector system showed 1.2 m.p. at breathing level of booth attendant, 115 m.p. inside duct above booth, 114 m.p. near inlet to cloth filter and 1.5 m.p. in exhaust stack from filter.

Lead exposures in mg. per 10 cu. m. were found to be 1.2 for "hand dipping," 6.8 for "removing hollow ware from mangle" (excess glaze rubbed off), 167 for occasional "frit making, hand shoveling," 18.7 for loading ball mill, 12.7 for loading rotary frit furnace, and 4.4 for spray machine operation. Two to 9 samples in each of these cases did not vary greatly from the mean except in the last (0.7 min. to 65.0 max.) where performance of exhaust and size of ware were the important factors.

Reduction of Dustiness—Through Boyce⁹ a contribution from Nichols¹⁰ on practical reduction of dusty conditions found during the conduct of the Kansas program covered, (a) the recommendation that granite and monument concerns utilize dust filters on sandblast exhausts which were usually found to discharge so close to buildings as to re-contaminate the enclosures. From one installation it was estimated that these should cost from \$30 to \$40

with negligible upkeep; (b) correction of a hazardous condition studied at a smelting and mining company where three pigments, leaded zinc oxide, zinc sulfate, and lithopone are made from lead and zinc sulfide ores. Slag from roasting the ores is crushed to cinder for roadbed ballast. During shovelling of slag the dust count revealed 18 m.p. per c.f. (70 per cent free silica). A rather simple procedure of wetting kept down a large amount of this dust, and after being recommended to the company, was followed.

Alteration of Essential Process—McCord¹¹ furnished an informative example of substitution of a non-dusty for a dusty process.

In offset printing, it is common practice to spray on each freshly printed sheet of paper a suspension of gum tragacanth, gum arabic, or starch in alcohol as an anti-smearing agent. The atmosphere becomes charged with gum arabic dust, gum tragacanth dust, etc. The can containing the mixture is placed 3' or 4' above the receiving rack on the press. With the arrival of each sheet automatically the valve on the can is tripped, and air pressure blows the gum mixture into the air and on to the sheet.

Due to exposure to this dust, and particularly gum arabic, a number of printers in divers shops developed asthma and whenever again exposed presented asthmatic manifestations.

It has proved practical to eliminate the sprays and to substitute a series of minute gas flames. This apparatus may be made by introducing a number of gas tips into a sufficient pipe length and affixing this with an automatic control to play flames upon the undried sheet for an instant without charring the paper or changing the color of the ink.

Conveying Collected Dust in Exhaust Systems—Hatch¹² prepared the following description of practical elements of design:

Dust captured at exhaust hoods is commonly conveyed to a central collector located some distance from the dust producing operations. The air stream itself is used to transport the dust, and for coarse materials and heavy concentrations high velocities are required. The most common pipe velocity is 4,000 f.p.m.

High pipe velocities are objectionable for several reasons:

1. The power consumption and operating cost are high.

2. The abrasion of elbows and pipes is rapid and maintenance therefore troublesome and expensive.

3. A careful balance of the system is required in order to insure proper distribution of the air flow and adequate transporting velocities at all points.

This balance is upset when any departures are made from the layout established in the original design. In addition to these disadvantages one must point out further that even a high velocity becomes inadequate if the material is wet or greasy. Thus it is difficult and expensive to obtain continuous operation of a dust exhaust system without plugging the exhaust mains with dust.

To obviate these difficulties hoods should be designed so far as possible to prevent the removal into the exhaust system of coarse material and the piping located so as to reduce to a minimum horizontal runs of pipe. If a header pipe is required in order to accommodate the several branch pipes, recent practice indicates that the header may be of large cross-sectional area, thus reducing the velocity to a low figure to insure a constant settling of material in the header. A chain drag or other suitable means must be provided to convey the settled dust to a suitable storage chamber. For a compact grouping of machines the low velocity header may take the form of a settling chamber with a hopper bottom for direct discharge of the dust without further conveying. Because of the negligible resistance in the low velocity header a balanced system is insured without regard to the location of the branches or change in location from the original layout. Connection to the fan and the dust arrester required for the fine material which escapes settlement may be made at any convenient point on the low velocity header.

The cost of mechanical conveying is high, and the main header of large cross-section is also costly, but against these one may credit:

1. Reduced power consumption
2. Abrasion of pipes and elbows eliminated
3. A balanced system insured

Mechanical conveying has been used in

exhaust systems in connection with wood-working machinery for several years, and is attracting considerable attention at the present time with respect to other types of dust. Installations which have come to the writer's attention recently included grinding and shaping machines for porcelain insulators, truing machines in abrasive wheel manufacture, dust control in cement manufacture, and crushing, screening, and conveying ore. The success obtained with these systems indicates this method of design will be used more in the future.

Extensive Alterations to Eliminate Lead Poisoning—Stratton¹³ outlined a case in which a concern spent \$25,000 to eliminate excessive exposure to lead dust of 200 persons among whom a number of serious lead cases had developed. Cast iron parts were enameled. A tunnel firing kiln used natural gas. The waste gases from the kiln fed the driers through which the sprayed parts passed on conveyers. Pumping the hot gases from the driers back into the spray hoods more than offset the total ventilation of the building through the spray hoods and other means. Lead dust was distributed throughout the premises.

A study was made, and through changes in fan capacity, duct diameters, and the installation of air curtains at spray booth openings, the amount of lead dust in air was reduced to a point of safety. Intensive medical and hygienic control of employees was maintained until constant checks of ventilation performance showed that they could work safely entirely unhampered, which convenience, together with the improved conditions, has probably more than repaid the expense.

Elimination of Plumbing Hazards—Connolly¹⁴ described examples of a common type of lurking exposure not likely to be considered by industrial hygienists unfamiliar with other branches of public health engineering.

A water pipe was found with its end submerged in a silver-plating tank

in a manner to make possible siphonage of potassium cyanide into the drinking water lines of the building if the supply pressure should fall below atmospheric pressure. Since these pressure drops are not rare, it was fortunate that this connection was changed to break any possible siphonage train before a combination of circumstances poisoned several hundred persons.

Continuity of connection was also ordered broken, in factories where water was circulated through water-cooled jackets and condensing coils of degreasers and terminated in pipes submerged in sewers, slop tanks, or vats containing various solutions.

Dust Reduction by Installation of Machinery—Pincus¹⁵ asked that a description of an accomplishment by their sanitary bureau be prepared by Tobias¹⁶ to illustrate the elimination of a dust exposure and possible silicosis exposure among 600 employees, of whom 12 sandpapered book edges by hand.

Dust was practically eliminated and 10 employees were released to another department by the installation of Paper Cutter, Model 265, of the Challenge Mach. Co., Grand Haven, Mich.,*

capacity 1,500 books per 7 hrs., knife cut 26", materials: old books to be renovated, stand operated with 2 employees at about \$4.50 each per day, cost 3.5 cents per book.

Cost Accounting*

A. J. MESSIER

*Business Manager, Los Angeles County Health Department,
Los Angeles, Calif.*

IN the administration of public health there are certain fundamental business principles which must be applied for the proper conduct of affairs.

In business and industry, particularly where the number of stockholders is large, there always exists a demand for accuracy as well as a desire for standardization of financial statements. Bankers loaning money to private business and corporations, and investment institutions arranging for new finances, have emphatically encouraged this trend. All parties concerned have recognized the value of having such statements audited by disinterested parties. The result of this has been the development of specialists, of properly accredited and trained accountants, engineers, and appraisers who play an active rôle in the interpretation of the component parts of financial statements in accordance with established procedures, with the ultimate result that accurate reports reflecting conditions are made in such a manner that their meaning is entirely clear—clear not only to the directors of the corporation and the bankers but to the rank and file of stockholders as well.

The business of public health is not a private undertaking without outside capital. It is administered with the funds levied on numerous taxpayers

who, as stockholders, have come to expect clear and concise statements on the expenditure of their tax dollar, just as they do from industry. As in business, the taxpayer finances accredited and trained personnel to the measure in which his confidence in that personnel is maintained. The taxpayer who holds his "stock" in public service and the one who is taking stock of public service is entitled to periodic, understandable statements and balance sheets. Further, the taxpayer-stockholder has recognized the value of having such statements audited and appraised by disinterested parties, but in many instances he is still in a quandary in so far as public health cost statements are concerned. He is deeply conscious that nomenclature is not as yet standardized and that per capita cost does not always necessarily mean per capita cost. He knows that there is quite a difference in degree of services performed that needs to be clarified so as to make public health cost comparisons really possible. He knows, for instance, that in one city the school health work is done by the health department as a regular activity of that department while in another city there may be a school health department maintained by a separate budget. He knows that in another city private or outside subsidy, such as Parent Teachers Associations, Visiting Nurses Associations, and tuberculosis associations, or a county charities department provide certain services

* Read before the Health Officers Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 28, 1938.

that must be performed by health departments in other cities not so fortunate with subsidies.

Many taxpayer-stockholders look to detailed "functional cost" for comparison rather than to "per capita cost." They have learned that functional cost is truly comparable only within a city, or within a county, because different cities and different counties vary in their conception or need of the functions sometimes compared. There is also a variance in local problems. Per capita costs ignore the need for increased functional activity in one area that is nonessential in another. For instance, tuberculosis control can be an important essential function in one area while in another it is of relatively little importance because of the freedom of influx of such cases. The same is true of health education. The taxpayer knows that there exists a vast amount of room for improvement on standard nomenclature as applied to functions performed in public health and that until nomenclature becomes more definitely standardized truly intelligent comparisons are an impossibility.

The Los Angeles County Health Department, with due consideration of the American Public Health Association's *Appraisal Form*, has developed a nomenclature to meet requirements of the Los Angeles County Health Department in its activities with 38 contract cities and a large unincorporated area. The code may not be regarded as the acme of perfection but it is definitely an index to the possibilities of a functional cost code for large cities or decentralized areas served from "health districts" or "health centers" which are in turn responsible to a central bureau of administration.

The code surely has served us well in those days when we were required to make detailed functional cost reports to those 38 cities and it has served

us as an administrative tool with bureau directors and district health officers. It is true that the code is now undergoing study for possible revision as a result of simplification of cost reports to cities made possible by a recent change in the California State Law whereby cities availing themselves of public health services from the county pay only for the services that are performed in the enforcement of local ordinances. This means that in so far as the contract cities are concerned they will require from us reports only as affecting enforcement of local ordinances and not pertaining to the various activities carried on by the health department under authority from the State Health Law.

The development of our "functional work number code" and the use of it will be interesting: Prior to 1917 the County of Los Angeles operated on a cash basis and although this means that the county did have some form of budgetary control it was not the effective control now exercised. The report of health department expenditures for 1916-17 reads simply:

Salaries	\$ 8,456.41
Other Expense	5,592.09
Outlay	340.77
	<hr/>
	\$14,389.27

The following year expenditures were \$14,506.14 for Salaries; \$7,077.12 for Other Expense; and \$1,572.80 for Outlay, or a total of \$23,156.06. This total, however, was expanded in detail to list seven functions, namely: Health Office, Administration, Conservation of Child Life, Treatment and Prevention of Communicable Disease; Food Registration and Inspection; Sanitary Inspection; and Suppression and Control of Venereal Disease. That year was really the beginning of our attempt at functional cost segregation.

In 1915 the County Health Department was housed in a single room tucked away in a relatively unused por-

tion of the erstwhile County Courthouse attic. Inasmuch as the staff consisted of but one man, Dr. J. L. Pomeroy, there were no complexities of organization. Functional cost keeping was not yet a problem. Control in communicable diseases over an area of mountain, desert, and valley covering 4,085 square miles was more than enough for one man (even if he did have a trusty or trustless Model X). Serving that large area presented problems enough without dwelling on cost accounting. Reports indicate that a considerable showing was made during that year and that the Board of Supervisors allowed the Health Department \$15,000 and augmented the force to include one inspector and one nurse.

As mentioned, budget control was installed in 1917 and the Health Department, still growing, was awarded about \$18,000. By 1919 effective demonstrations had been made, notably in the suppression of a typhoid epidemic, and those sound practices inaugurated by Dr. J. L. Pomeroy resulted in the signing of contracts for public health by two cities, namely, Pomona and La Verne. By 1922 Glendora, El Segundo, and El Monte sought contracts. The following year Alhambra, Hawthorne, Monrovia, and Whittier signed contracts. In 1927, 26 cities were under contract and the following year 6 more were served. In something like 12 years the department had grown from a budget appropriation of approximately \$15,000 to approximately \$1,000,000.

To cope with rapidly increasing needs for the accumulation of definite statistical data which were required for administrative purposes for reports to contract cities and for state and federal agencies, mechanical tabulations of information on births, deaths, morbidity, inspections, home visits, etc., were provided with the introduction of a punch card, mechanical sorter, and tabulator, and when the various Mayors and City

Councilmen became cost conscious, as a result of changing contract rates, clauses were inserted in the contracts requiring periodic functional cost reports as well as statistical reports covering the various activities within their respective boundaries. Naturally, the cities were interested in seeing just how much service they were paying for, and exactly what those services cost.

The punch card system was then extended to take care of the recording of time and mileage on the same card that was used to collect statistical data. This work number code, devised by Dr. Pomeroy, was put into use and with modification or addition has been in service for more than 10 years. The value of the accumulation of functional cost data is exemplified in that such functional cost data served the department at periodic contract periods to increase the revenue of the health department from such contract cities and specifically that revenue was increased during the 10 year period of 1926-1936 from \$40,000 to \$102,000. This money, incidentally, did not accrue to the Health Department budget but was deposited to the credit of the County's General Fund.

The compiling of functional cost data also has served in the preparation and fortification of budget requests which have passed the scrutiny of the Department of Budget and Research, which is charged with the examination of each item requested, and enables us to present in graphic form certain data not readily obtainable otherwise. Often, we have reduced results to a single chart, and in one notable instance not so long ago a single chart played a tremendous part in "selling" a tuberculosis program.

The same cost consciousness that is manifested by the city fathers, the research workers of the Department of Budget and Research, is shared by the taxpayer-stockholder, as exemplified at

various hearings of taxpayer's associations when the budget is considered by the Board of Supervisors. The value of accumulative history of functional cost over a period of years is therefore clearly evident.

Briefly, the main headings of the functional code used are as follows:

BUREAU OF GENERAL ADMINISTRATION

10 *Health Officer*

Used by Bureau Directors and District Health Officers representing Department as a whole

11 *Executive*

11.01 Secretarial and Personnel

11.02 Business Management

11.03 Special Work Annual Reports

11.04 Research Work

All administrative research assigned by Health Officer or Business Manager

12 *Accounting*

12.01 Accounts

12.02 Records and Statistics

12.03 Unit Costs—Population data, etc.
Cost Section

13 *General Popular Health Information*

13.01 Press Work

13.02 Health News and Bulletins

13.03 Motion Pictures

13.04 Exhibits and Demonstrations

13.05 Lectures and Talks

14 *Employee Training*

15. *Vital Statistics*

18 *Maintenance*

18.01 Storeroom

18.02 Delivery Service

18.03 Special Assignment

18.04 Salvage

18.05 Service of Repair

18.06 Ditto Copy Work

18.07 Mimeograph Copy Work

Medical & Social Service, Maternal & Child Hygiene, Sanitation, Communicable Disease Control, Laboratories, etc., all have their major code numbers with sub-numbers covering such other breakdowns as it was deemed advisable to make.

As to material and supplies, the County Health Department added in 1932 a classification of supplies for material control ledger and code numbers

were assigned to the various items used by the department. This classification was also used through the operation of the mechanical tabulating equipment. Perpetual inventory figures are readily accessible and assure the reasonably prompt preparation of reports as needed. Further, we know at all times the actual money value of our store stock.

The punch card system has been decidedly useful in the accumulation of billing data in conjunction with inter-departmental services to other departments. These services amounted to over \$56,000 during the fiscal year just ended, which accruals are deposited with the County Treasurer and not to the credit of the Health Department Fund. Under the existing arrangement the County Health Department acts as custodian for several county buildings in which others beside the County Health Department offices are located and detailed billing information available to the various departments served must be maintained.

Any license or tax fees collected as a result of public health services do not accrue to the Health Department Fund but are deposited with the County Treasurer as miscellaneous receipts and accrue to the General Fund of the County. As to the cost of cost accounting, particularly with municipal, county, or state departments, it is clearly evident that no definite comparison with other cities, other counties, or other states can be made when we take into consideration the fact that one city may be able to operate under a very liberal setup which permits expediting the handling of claims whereas other cities or counties are definitely held by rigid charter provisions put into force under conditions less modern than the present and continuing with the ramification of detail which cannot be eliminated except by revision of charter provisions or changes in rules ordinances which govern in certain cities and counties.

We do not propose to answer the possible question as to whether or not a punch card system of mechanical tabulation is entirely practical for a health department, considering mechanical tabulating and sorting for functional cost data alone. Volume can best determine that. For statistical tabulations, however, the mechanical setup provides unquestionable flexibility. Our own volume of statistical data required is such that we believe we have reached the bottleneck point where, in order to render coincidental reports on cost and statistics, we must either enlarge our present mechanical setup to permit more epidemiological studies, more spot checks, more studies of birth and death records, more complete information on tuberculosis, and more

statistical information on venereal disease control, or use our present equipment entirely for statistical purposes. With the assistance of the County Auditor, we are experimenting with a system which indicates a promise to liberate mechanical tabulating time to statistical information and to separate time and mileage from such statistical reports. We are not prepared to make a prognosis and the next few months probably will tell the story.

In conclusion, we should like to stress again the point that a concerted effort is needed to bring about the standardization of functional terms used in connection with public health departments and thus so clarify the situation as to make comparisons truly possible.

DISCUSSION

HENRY F. VAUGHAN, DR.P.H., F.A.P.H.A.

Health Commissioner, Detroit, Mich.

DR. POMEROY, Mr. Messier, and their associates at the Los Angeles County Health Department have built up a very excellent means of cost accounting. It seems obvious that the establishment of such a service is of value in the reallocation of costs to various localities which purchase their public health service from a central organization. There should be an increasing tendency for suburban communities either to pool their health work through a common agency, county or district, or purchase the same from some nearby urban center. In either event the need of reapportionment of costs is evident.

In Los Angeles County both the extensive area involved and the multiplicity of organized communities warrant the adoption of the plan whereby the services are pooled under the

auspices of a county unit. In suburban communities which cluster about a large metropolis the control of milk, food, sanitation, and even communicable diseases by the city may serve to a liberal extent the needs of the surrounding territory. Surely, it would not be unfair to apportion some of this cost back to the suburban taxpayers. To do so requires the installation of a cost accounting system.

In the sanitating of food, milk, and other beverages a health department provides service not only for the consuming public but also for the industries, food handling establishments, pasteurizing plants, and packing houses concerned with such problem. In apportioning the cost of inspection the broad attitude may be taken that the suppression of disease is in the interest of the public good. The cost must in

the final analysis be borne by the public. The actual bill for the service may, however, be presented to the consumer either as a taxpaying citizen or through his milk and meat bill. We, personally, feel that from the administrative viewpoint of the health department there is some advantage in establishing licensing fees sufficiently high to meet a good share of the inspectorial expense. After all, the practical health administrator knows that there is a reasonable limit beyond which public funds will not be appropriated for the health department. It behooves us then to use our ingenuity in transferring from our tax budget to some other source those expenses which can be reasonably borne elsewhere.

There are many activities which have a complete or partial health significance which can be shared with other city departments or with industry and business. Plumbing and smoke inspection, as well as traffic control, all have their health significance, but if we can impose upon a building department and police department the expense involved in engaging the services of inspectors and policemen, it reserves to the health department, funds with which to employ nurses and health educators. We must conduct our health programs with maximum service in adventures which contribute most directly to reductions in death rate, prolongation of human life, and an increased fullness and wholesomeness of man's existence. In sharing with others, by the official or

nonofficial, public or individual agencies, we need some reasonable form of cost accounting. The consumer, the businessman, and the public demand this type of bookkeeping.

Financial interpretation of health procedures affords also an opportunity for the alert health officer to compare his own program in point of time and that of others in both time and place. As the years roll by we should be interested in knowing whether our departments are becoming more efficient and whether the cost of a nursing visit or an inspection is going up or down. If it is too high in light of previous years or too high when compared with similar conditions in some other city or county, let this serve as a warning note that the service needs investigation. The whole process should serve toward the more efficient conduct of public affairs.

Finally, let us not forget that the modern health department is built upon public confidence, that the citizens support a health department because of their personal interest in the avoidance of conditions which are inimical to health. Public funds would soon dry up and health departments would be stranded were it not for some systematic reporting to the taxpayer of the value received from the tax dollar. Those who have taken an interest in this type of health bookkeeping are to be congratulated. Let us hope that their example will be followed by many others.

Essentials of Budgeting*

WALTER N. KIRKMAN

*Chief, Division of Personnel and Accounts, State Department
of Health, Baltimore, Md.*

ACTIVITIES of health departments are expanding rapidly, in consequence of popular demand and increased appropriations. Almost universally, appropriations are requested in budget form, and accounting procedures are based on the accountability of funds allotted under budgets. The budget record is probably the one form which is used in common by all health departments, large and small, and operating in states, counties, and cities. So the budget is the most important financial document in the department. And, since all activities cost money and, therefore, have a financial basis, it can be said that the budget is one of the most important instruments in the entire department. It is timely, therefore, that at this meeting of the Health Officers Section, where business administration subjects are discussed for the first time, that "The Budget" should be given prior consideration.

The subject will be developed under the 4 following general heads:

1. Budget Planning
2. Budget Building
3. Budget Accounting
4. Budget Control

BUDGET PLANNING

Budget making begins with *planning*. The *financial* budget is the device for making effective the *work* budget. The budget is the *effect* not the cause.

* Read before the Health Officers Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 28, 1938.

Budget making time should be an inventory taking time. Existing activities should be critically reviewed and evaluated. Results should be compared with costs, and determination made for contraction, continuation on the same basis or expansion of existing activities. Constant repetition of duties is apt to establish their necessity in the minds of the workers. Just because something has always been done is no reason, *per se*, for its continuance. A tradition may become sacred solely by reason of its age. It is desirable, therefore, that the public health administrator critically examine the activities of his department at budget making time, and seek continued support of only those which have made definite contribution to the main objectives of public health work. Having made this important determination, it then becomes necessary to consider the extent, if any, to which present activities should be extended and what new activities should be inaugurated. Pressure for new activities in public health work frequently originates from the lay public and careful consideration should be given to such suggested projects, to determine their soundness as governmental procedures and their position or relation to functional units in the organization. Of course, new activities will also be suggested by our own experience or that of others, and by scientific research and discoveries.

In this connection I quote from an article by Dr. C. E. Waller, Assistant

Surgeon General, U. S. Public Health Service.¹

Sound planning is essential to the success of any public health undertaking. It is unscientific and wasteful to attempt the setting up of facilities for health work without first determining what the most important needs of the community may be, and how each dollar available to the health organization may be expended in such manner that the greatest possible return on the investment may be obtained. Too often the development of administrative machinery and procedure has simply followed the lines of a pattern borrowed from some other community, or, even worse, has been based upon expediency. Any plan designed to meet the health needs of a particular state, city, or county should be formulated only after careful study has been given to all available data relating to local health conditions, including morbidity and mortality records, and after the most important problems have been determined. It is well to bear in mind, in this connection that some of the activities usually carried on by health departments, while popular, and desirable from the esthetic standpoint may be relatively of little value in actually preventing disease. When funds are limited, the facilities required to meet the most important needs from the standpoint of reducing preventable illness and mortality should come first; after these have been provided, other activities may be undertaken, but the public should be informed very frankly that some of them are desirable chiefly for esthetic reasons or for the sake of comfort, and play only a small part in protection of the public health. Such activities should be afforded to the extent that the people are willing to pay for them after funds have been made available to meet the real and urgent public health needs of the community.

We must also consider, in selecting health activities to be supported with public funds, the question as to whether the proposed expenditure for a given project is sound from an economic standpoint. It is conceivable that in some communities the performance of certain functions, admittedly of some value in preventing disease, might not be economically profitable because of the relative unimportance of the problem and, consequently, the relatively small return for the expenditure. Those of us who have the responsibility for the administration of public funds should have the courage to face the facts and to be fair with the public.

Determination having been made concerning our activities or *work* budget for the ensuing period, it then becomes necessary to support that program with a *financial* budget.

This leads us to a consideration of the second phase of budget making, namely, budget building.

BUDGET BUILDING

In compiling the budget, it is necessary, of course, to follow the form provided for all agencies of that government of which the health department is a part.

The form varies in the several states, counties, and cities. This renders somewhat difficult the comparison of health department budgets. It may be possible for this group to work toward a standardized terminology of items so that health department budgets can be more accurately compared. In many of the states, counties, and cities using the budget system, a standard classification of expenditures has been adopted. This differs considerably in the various political units, some classifications being very detailed, others comparatively simple. In general it is believed the system described below fairly meets the needs. Only that part of the classification relating to health department operation is discussed. The plan is effective in several of the states, and has stood the test of usage over a period of several years. Under this plan the classifications governing the preparation of the budget require the estimates to be furnished under the two general classifications: by character of expenditure; by object of expenditure.

Classification by character of expenditure means the division of the estimates in the budget so as to distinguish between current expenses, or those which are incident to operation, and those which are capital outlays. Requests for funds for each activity

are made under one or the other of two heads—"expenses of operation" or "capital outlays."

"Expenses of operation" embrace all items of expenditure necessarily incurred for current administration, operation and maintenance, and those for materials and equipment in the nature of repairs or replacements which do not add to capital assets.

"Capital outlays" comprise expenditures of every character which increase capital assets by additions or betterments. Extensive or extraordinary repairs and replacements in kind do not constitute "capital outlays" where no change has been effected in the kind of equipment, or structure.

Following the primary separation of the estimates for each distinct activity into "expenses of operation" and "capital outlays," the items which fall under each head are arranged by *object* of expenditure—or, to express it differently, by kind of things purchased—in accordance with the following general classification, which is uniform for all activities.

EXPENSES OF OPERATION

A. Personal Service

Personal service is direct labor of persons.

Salaries

Salaries to include compensation of all regular officers and employees who are paid at a weekly, monthly or yearly rate.

Wages

Wages to include compensation of all regular employees who are paid at an hourly or daily rate.

Special Payments

Special payments to include all fees paid for special services.

B. Supplies

Supplies are commodities of a consumable nature which show a material change in, or an appreciable impairment of, their physical condition through use; and instruments and tools which have a limited period of use and are liable to loss, theft, and rapid depreciation.

Operating Expenses

Fuel supplies

Office supplies and stationery

Printing

Medical and surgical supplies

Laboratory supplies

Household, laundry, and cleaning supplies

Motor vehicle supplies and operation

Books and periodicals

Engineering supplies

Vaccines and antitoxins

V. D. Clinic supplies

Other supplies

C. Repairs and Replacements

Includes the cost of labor and services of other than employees, materials, use of equipment, etc., all of which may be necessary to maintain in kind equipment and property.

D. Other Expenses of Operation

Light, heat, power, and water

Traveling

Transportation of commodities

Communication — telephone, telegraph, postage, etc.

Insurance

Other Expenses

E. Capital Outlays: Betterments

Equipment, land and structures (additions)

Equipment, consists of machinery, implements, tools, furniture, live stock, vehicles and other apparatus that may be used repeatedly without material impairment of their physical condition and which have a calculable period of service, including additions or betterments to existing equipment.

According to A. E. Buck in his book *Public Budgeting*²:

The systematic classification of governmental expenditures and income is a recent achievement in this country. Perhaps the first comprehensive attempt at any such classification was that made by the U. S. Bureau of the Census when it began the collection and publication of the Financial Statistics of Cities under an act of Congress which was passed March 6, 1902. Under this classification, expenditures were grouped on both functional and character bases and income (revenue) was arranged according to sources. The same types of classification were applied to the Financial Statistics of States when this series was started by the Bureau of the Census in 1915.

The next important development in classification came as a result of the work of the New York Bureau of Municipal Research in connection with the installation of budgetary procedure in New York City. This work began in the city department of health in 1908, and during the subsequent five or six years practically all the departments and

agencies of the city government were studied. The proposals for classification were confined to expenditures. At first, the emphasis was placed on a functional classification within departments supplemented by an object classification. Within a short time, however, the emphasis was shifted to the object basis. The reason for this, as later explained, was that classification by object lends itself to standardization of accounting procedure, while grouping on the basis of function seems to increase the difficulties, inasmuch as the functions must differ in every department. Accountants naturally preferred the form of classification that promised greater uniformity and order in the account. It was possible to standardize the classification by objects but not the functional one. Besides, appropriations by functions would leave the door open for the misuse of funds, unless supported by an intricate system of accounts; while appropriations by objects would apparently check this practice, which was regarded as one of the most trying evils of that period. For these reasons the functional classification was gradually subordinated and the classification by objects became the primary one in all the city departments by 1912.

Having decided on the *work* budget and drawn the pattern for the *financial* budget, it now becomes necessary to determine the amounts to be asked for in the various items. In the personal service division of the budget, the amounts asked for individual salaries should again be the result of careful planning. It is presumed that job studies have been made from time to time to determine, among other things, the load and the production per worker, and the relationship of the duties to be performed. Useful also, is some device or measure to determine and record the efficiency of employees in their respective jobs. With this information and background, it is now possible to fix the amounts of individual salaries. Involved in all this, of course, are certain aspects of personnel administration, and it is to be presumed that in the selection of employees, job classifications have been established, and duties of each position and qualifications of persons holding the same have been defined. It is also to be presumed

that proper tests have been applied to individuals seeking employment to determine their fitness. If the department operates under civil service, these procedures almost surely will be in effect. In this connection, it can be said that while there are some objections to the operation of civil service systems, particularly in the employment of professional and technical personnel, the desirable features distinctly outweigh the undesirable ones. Security of employment enlists the interest of qualified personnel, and emphasis is placed on job classification, definition of duties and qualifications, and orderly and impartial testing of applicants for positions to determine their fitness. This makes for good personnel administration.

Budget building will be greatly simplified if there is in effect a standardized scale of salaries. Like salaries should be paid for like duties and *performance*. It is desirable to have a range in each classification, and, generally speaking, new employees should enter the service at the minimum rate and be advanced as their efficiency increases.

It is customary to have a differential of from 20 per cent to 30 per cent between minimum and maximum salaries within the various classifications, and to establish yearly increments so that the maximum is reached in five years. Some salary standardization plans provide an additional amount above the maximum as a bonus, for extraordinary or unusually efficient service.

All of these features of good personnel administration can be adopted by any department, irrespective of whether or not the political unit under which it operates uses the merit system.

With these administrative procedures in effect, the fixing of the amounts of the individual salaries in the budget becomes a simple matter. It is for this reason that it can be said that

the salary budget is the result of an orderly and planned approach to the important matter of compensation. We are dependent upon others to do the routine work of our departments. Good morale is not only important in the successful conduct of any organization, it is absolutely necessary. The payment of fair and just compensation in turn has a large effect on morale. Just as important is provision for a retirement system to insure some degree of economic security to those who have devoted their lives to this essential branch of public service. Public employees are of course exempt under the provisions of the Social Security Act, relating to Old Age Pensions, so it behooves us to work for the establishment of pension systems in our own political units.

In determining the amounts of the various expense items, both the past and the future must be explored. The past for experience in the consumption of the quantities of commodities or use of services which we have purchased. In this connection it is presumed that records of use of commodities have been maintained as an index of future consumption. Proper weight must, of course, be given to expected increase or decrease in consumption or use. Consumption and use having been determined it then becomes necessary to estimate the cost. Here we must explore the future, and forecast market conditions from past and present price trends, and other economic factors which affect the price structure.

Having fixed the individual budget items it is now possible to total salaries, to total expenses, and arrive at a grand total. These sub-totals should be critically reviewed for their relationship to each other and to the grand total; for there is a relationship between total salaries and total expenses and the grand total. For example, in Maryland we have found that total salaries should

not exceed 74 per cent of the total budget and should not be less than 70 per cent. If too large a sum is set aside for personnel services we will have workers but no tools; if too large a sum is provided for expenses, we will have tools but no workers. So, it is necessary to keep the two main divisions of the budget in proper balance. This percentage relationship will be constant only for each political unit, and must be worked out by each department for its own use. State departments because of the large area in which they work, need a larger amount for expenses, particularly travel and communication, than counties and cities. Costs and convenience of travel and degree of decentralization of field work are other factors which affect the percentage relationship of budget subdivisions. This test should be applied to the budget sub-totals and adjustments made if necessary.

It is interesting to observe that 28 states report the relationship of sub-totals for salaries and expenses to total budget to range from

35%	for salaries and
65%	" expenses
<hr/>	
100%	
	to
81%	for salaries and
19%	" expenses
<hr/>	
100%	
The average for salaries is 61%	
and for expenses is 39%	

Seventeen of the larger cities report salaries totaling from

36%	for salaries and
64%	" expenses
<hr/>	
100%	
	to
92%	for salaries and
8%	" expenses
<hr/>	
100%	
The average for salaries is 77%	
and for expenses is 23%	

Because of varying conditions and factors perhaps not much significance can be attached to these average figures.

The budget having now been completed and all the tests for a balanced document applied, it becomes necessary to prepare for its explanation and justification before budget making and appropriating authorities. In no one particular perhaps is the result of careful planning and proper building technic so forcibly illustrated as in the presentation of the budget. A haphazard or poorly organized affair is sure to bring discredit on the department, and little consideration from the authorities. By the same processes of planning and building we should be able to justify our budget to fiscal officers. Nothing so far has been said about cost accounting because that is the subject of another paper for presentation at this session. It is highly desirable to be familiar with the unit costs of operation, at least of the various functional units. If unit costs have in addition been developed for individual activities or processes, that information can be used to good advantage to justify the budget to fiscal and appropriating authorities.

BUDGET ACCOUNTING

We assume now that the budget has had the approval of budget making officials, has successfully run the gauntlet of appropriating authorities, and the funds are available. Activities of the department are proceeding and money is being expended. It now becomes necessary to account properly for such expenditures. It is not within the scope of this paper to describe complete accounting systems for health departments. But if funds are made available under a budget it is obviously necessary that a budgetary record be maintained. This is one of the accounting forms which doubtless all health depart-

ments operating under the budget system have in common.

A satisfactory form provides for the recording of encumbrances, expenditures, accretions in way of appropriated receipts, and, of course, shows the amount, account number, and title of the budget item. One sheet is used for every item. Accumulative totals of receipts are shown and accumulated expenditures and encumbrances, and finally net balances after each transaction.

This form can be used in connection with hand or machine bookkeeping. Appropriations are authorizations to spend, and this form provides a complete record of expenditures bringing together all the necessary information, including accretions to the various items, and showing unexpended and unobligated balances after every transaction.

Budgets must necessarily be prepared some time in advance of their date of operation and it is impossible to forecast exactly the correct amount of every item. As the budget period proceeds, some items will carry surpluses, others will indicate deficits. This is especially true of budgets for health departments, where unpredictable outbreaks of disease may throw the most carefully planned budget out of joint.

Provisions must therefore be made to amend the budget by adjustments between surpluses and deficits, in order to balance at the end of the period. Practice, of course, differs in various political units, and the procedure in effect must be followed. The important point is that flexibility in budgets must be provided if funds are to be used to the best advantage. It is also desirable to have a contingent fund, under outside official control if necessary, which will be available to meet actual emergencies, especially those arising from unusual outbreaks of disease. This fund

can be sufficiently safeguarded to prevent the possibility of the money being used except in absolute emergencies.

BUDGET CONTROL

As budget items are authorizations to spend, by that very factor expenditures must be limited to the amounts of the items. So that the budget appropriations become at once authority and restriction. Penalties are usually provided for over-expenditures, so it becomes necessary for the administrator to establish the machinery for control of expenditures. Without this device, the financial situation would soon become chaotic. Functional units should be allotted their own budgets; and obligations and disbursements carefully recorded against every item, so that

rates of expenditure can be observed. Rates of expenditure have some importance but are not necessarily controlling. Seasonal activities, forward purchases of supplies in favorable markets, and other factors disjoint the rate of expenditure from the theoretical 1/12 of the annual appropriation per month. These disjointed rates however, tend to flatten out over a period of months, so that the trend of the rate can be established. By such safeguards, it should be possible to balance activities against resources and reach the end of the budgetary period with accounts balanced.

DISCUSSION

CLIFFORD C. SHORO

Administrative Finance Officer, State Department of Health, Albany, N. Y.

MR. Kirkman has made it perfectly plain to all of us that there are two important preliminary steps to the completed budget. First "Budget Planning" and second "Budget Building." Then he carries his scheme to third, "Budget Accounting" and fourth, "Budget Control," and there he stops, and I am glad because he has so completely covered the subject that there is not much left for me to talk about. I might comment on the order in which he has placed the four sub-headings into which he divided the subject, because it seems to me that "Budget Control" might precede "Budget Accounting."

But I really do believe that there is one important phase of "Essentials of Budgeting" that he has not brought out.

I mean the philosophy of the fiscal officer in preparing his budget for submission to the appropriating authority.

You know that a *budget* is actually a financial plan of a governmental unit which covers not only appropriations to be requested but also ways of financing such proposed expenditures. Or, in other words, a budget is a plan of expenditures and income.

My philosophy of budget making can be summed up to this, "Budget only such items and in such amounts as can be defended before any individual, group, or committee by factual data." I have found that different methods are employed by health department and hospital officials in presenting their plans and budgets for consideration. However, I can safely say that all methods used can be classified under two

headings (1) the true or honest budget that can be defended to the last detail, and (2) the inflated or padded budget.

First, let me discuss the latter method of budgeting. Some officials feel that their budget must be prepared in such a way and in such amounts as will give room or opportunity for the appropriating authority to cut and slash and still provide sufficient funds on which to operate. They feel that this is the only safe method to use as it provides an opportunity for the official charged with the duty of making or recommending appropriations, be it the governor or legislature of a state, the mayor or board of aldermen of a city, or the board of supervisors of a county, to publish the budgets submitted as compared with the appropriations made or recommended calling particular attention to the savings made to the taxpayer.

I do not agree with this method.

I believe that the inclusion of "velvet" in a budget is sure to be detected and will result in the entire budget being viewed with suspicion and distrust. Such a budget is sure to be reduced and the fact that some items and amounts are absolutely necessary and essential will not deter the appropriating authority from arbitrarily reducing the entire budget.

I will stake my chances on a true and honest budget but will not jeopardize the operation of our department by the submission of an inflated budget.

If a new activity is worthy of consideration then it is worthy of sufficient study and planning so that a request for an appropriation with which to implement such activity can be properly defended and not subject to reduction on account of poorly estimated costs. If estimates of costs of maintaining a service or activity are carefully made and can be backed up with factual data or, in the absence of actual facts, can be reasonably and honestly com-

pared with data of a comparable activity already under operation, then the decision to be reached before an appropriation is made can be based on only one consideration, namely, is it a necessary or essential activity which the governmental unit should undertake for the benefit of its citizens.

If it is proposed to extend or enlarge an activity already in operation then it becomes a comparatively simple matter first to determine the extent or volume of work to be done or services to be rendered and by comparison with the activity already under operation to determine the cost of the enlarged program.

We have considered the two opposite methods of preparing budgets for consideration.

There are other types of budgets that are submitted, possibly less frequently, but yet we do see them occasionally.

Take for instance a plan or program submitted by a division to be included in the departmental budget. Invariably the greatest amount of detail is given to explanation of the needs for the activity and the personnel with which to carry it on. If it is a field activity the plan will include the necessary field personnel, automobiles for transportation, items of maintenance and operation of cars, and hotel and other expenses of travel, and statistical, stenographic and clerical assistants in the office; but I wonder how many fiscal officers in checking such a plan have found that nothing has been included for the purchase of office furniture, typewriters, filing cases, etc. I once saw a budget that had been prepared calling for the expenditure of over \$100,000 and in listing the personnel required, not one single position had been included to do the necessary auditing and accounting of this fund.

In his treatment of the subject under discussion, Mr. Kirkman has included Budget Accounting and Budget Control

as equally important as Budget Planning and Budget Building. In this I fully concur. It is accepted that the planning of the budget is the prerogative of the Chief Medical Officer. However, the building, control, and accounting of a budget should be the duty and responsibility of the fiscal officer, which brings me to the point that I want to make in connection with the relation between the chief health officer and his fiscal officer. Possibly this has no place in this discussion, but I have cited two examples of incomplete budgets simply to give me an opportunity to stress the fact that your fiscal officer should have as important a place in your official family as any other division head.

His should be the responsibility for the execution of a complete budget. His should be the authority for the proper and economical expenditure of all funds appropriated for the department for expenses of operation and his the responsibility for budget accounting. No budget should be prepared and submitted as a request for appropriations that has not been built by the fiscal officer on plans laid by the chief medical officer.

Likewise, no orders for the expenditure of funds appropriated under any

of the several headings of Expenses of Operation should be issued by any department official other than the fiscal officer. Only in this way can the financial affairs of a health unit be properly conducted.

As an indication that health officers are coming to realize the assistance that a well trained fiscal officer would be to them I call your attention to what some speakers have said earlier in the week.

Dr. Mosher recommended the delegation of administrative authority by the health officers. Dr. Mountin called our attention to the average tenure of office of the health officer. Dr. Waller pointed out the probability of increase in federal appropriations and allotments to states for general public health work and for specific purposes. This had reference to the program that Dr. Parran so thoroughly explained. Dr. Bass said that a doctor has the reputation of being a poor business man. Dr. Williams made this statement: "fortunate indeed is the health officer who has a strong financial and budgeting secretary." Dr. Amyot in connection with his recommendation of a committee on finance, budgets, and business administration referred to it as the "life blood of the organization."

WILLIAM HALLOCK PARK

THE death of Dr. Park on April 6 breaks one of the last remaining links with the Golden Age of Bacteriology. His 76 years spanned the entire history of the modern public health movement; and his personal experience, as the organizer of the first municipal diagnostic laboratory in the United States and as its active head from 1893 to 1936, is a unique record of achievement.

Dr. Park was born in 1863 and graduated from the college of the City of New York, taking his medical degree at Columbia in 1886. He studied at Vienna and began general practice in New York; but he brought with him from abroad the new vision of bacteriology and began, under Dr. T. M. Prudden's leadership, to experiment with the bacteriological diagnosis of diphtheria. Dr. Hermann M. Biggs, who had recently been appointed Chief of the Division of Pathology, Bacteriology, and Disinfection in the city Department of Health invited the youthful investigator to organize his projected laboratory. Park began service on May 4, 1893; and by the end of that calendar year he was able to make one of the most remarkable reports in the history of bacteriology. His first 8 months of study demonstrated: (1) the validity of the culture test as the only reliable criteria for the diagnosis of diphtheria; (2) the persistence of virulent diphtheria bacilli in the throats of convalescents; and (3) the importance of the well carrier in the transmission of this disease. The value of the latter contribution to the development of our understanding of the importance of the carrier state has never been appreciated at its full value.

During the next 4 years, Park and Biggs employed diphtheria antitoxin for the first time—on a large scale—for the treatment of diphtheria and completed the first statistical demonstration of its incalculable value. Later on, when active immunization against this disease became a possibility, it was again Park who took the lead in the development of toxin-antitoxin. His intimate connection with this field is indicated by the fact that our standard organism in all diphtheria studies is still "Park No. 8"; and it was truly said that Dr. Park

"contributed more than any other living man to the development of bacteriological diagnosis and serum treatment which has made possible the conquest of diphtheria."

Yet Dr. Park was no "one-disease man." In connection with the immunological prophylaxis or treatment of scarlet fever, of pneumonia, of tuberculosis, of pertussis, of meningitis, of poliomyelitis, his achievements are embedded in the permanent literature of medical science; and he played a notable part in the introduction of immunization by the use of convalescent serum in measles and other infections.

In the wider field of public health, Park conducted (with Dr. Emmett Holt) one of the first studies of the relation of milk to infant diarrhea. He added greatly to our knowledge of human infections with the bovine tuberculosis bacillus; and he was the outstanding figure in the development of methods for the bacteriological control of municipal milk supplies.

Dr. Park received well deserved honorary degrees from New York University, Queen's University, and Yale. He served as Professor of Bacteriology at University and Bellevue Hospitals and at the Medical College of New York University, and in 1933 was appointed as Hermann M. Biggs Professor of Preventive Medicine at the New York University and Bellevue Hospital Medical College. His texts, *Pathogenic Microorganisms* and *Public Health and Hygiene* have made his influence as a teacher nation-wide. Among the honors showered upon him have been the presidency of the American Public Health Association, the Society of American Bacteriologists and the Society of Experimental Pathologists. He received the Sedgwick Memorial Medal of the American Public Health Association, the Kober medal of the Association of American Physicians, the Public Welfare medal of the National Academy of Sciences, and the Townsend Harris medal from the College of the City of New York.

To attendants at the annual meetings of the A.P.H.A., Dr. Park was much more than a great figure in the history of bacteriology. To his staff in New York City, he was an inspiring, loyal, and affectionate chief. To many more of us, he was a wise critic, a sane counsellor, a modest, genial friend. We can agree with the citation made in connection with his honorary degree at Yale that here was "the perfect type of the scientist in the service of the State."

REVISING HISTORY

ONE of the most dramatic instances in medical history was the conquest of puerperal fever. Nothing arouses people more than such a terrible death rate as used to occur in childbirth—an entirely normal and physiological function of life. America was the scene of one of the bitterest controversies in which one party forgot the amenities of life. The other party to the controversy gave a "soft" answer in saying, "No man makes a quarrel with me over the counterpane that covers a mother, with her new-born infant at her breast." To Oliver Wendell Holmes we in America are accustomed to giving credit for the discovery that puerperal fever was a contagious disease and his article published in April, 1843, is one of the classics of medical literature. He said: "The disease known as Puerperal Fever is so far contagious as to be frequently carried from patient to patient by physicians and nurses." In Europe credit for the

discovery is usually given to Semmelweis. It is perfectly true that Semmelweis made observations and devised a system of prevention of childbed fever which was markedly successful. In May, 1847, he used "chlorina liquida" to wash his hands and required all of his students to do the same.

Now we have a story from Budapest* which seems to be thoroughly authenticated. In 1923, Professor Hauch, of the University in Copenhagen, claimed that the discoverer of the cause of puerperal fever was Pehr Gustav Cederschjöld. Professor Györy, of the Department of Medical History, University of Budapest, resolved to defend the claim of Semmelweis and undertook an extensive study which has ended in his giving the credit to Cederschjöld, who was born in Lidboholm, Sweden, in 1782. In 1817 he was appointed extraordinary professor of obstetrics and adjunct of the lying-in hospital Allmänna Barnbördshuset, founded in 1775.

Puerperal fever was common in the 18th and 19th centuries in the Scandinavian countries. At Allmänna Barnbördshuset the mortality for the first 2 years was 2 per cent while in 1777 it jumped to 19 per cent, though a new building had been moved into, and after that the disease was constantly present in the Institute. Cederschjöld pointed out that the fever was capable of assuming lasting epidemic character in large lying-in hospitals. He thought it was spread through the air by means of a volatile agent. He described the disease as assuming the picture of putrescence of the womb, but believed that the contagion clung to the nurse who carried it to healthy mothers on whom the same sponge or towel was used. He told of having seen almost all puerperal women treated by a certain midwife fall sick, so much so that he was forced to exclude her from the obstetrical wards, while the disease was practically absent from women attended by other midwives. Cederschjöld, acting on the belief that contagion was spread from the vulva, supplied every patient with a special sponge and towel. Almost immediately favorable results appeared. In 1826 he was allowed the use of three wards wholly separated from the lying-in institution, to be used exclusively for women with fever. They had separate nurses and midwives. A little later he mixed chlorine with the water with which the parts of women were washed. This account was given in 1839. Semmelweis's discovery was made in 1847.

Apparently Semmelweis did not know of Cederschjöld's work. It seems certain that Cederschjöld deserves a distinguished place in the long line of observations and studies which ended in the discovery of the cause of puerperal fever and its prevention.

According to the evidence, we must admit priority for Cederschjöld. Just as certainly, Holmes preceded Semmelweis in his understanding of the contagious character of the disease. It is evident that three great men each made a great discovery independently, and honor must be paid to each one of them for a notable service to humanity.

* Foreign Letters, Budapest, *J.A.M.A.*, Feb. 11, 1939.

GUARDING THE HEALTH OF VISITORS TO THE NEW YORK WORLD'S FAIR

THIS greatest of all World's Fairs, according to the publicity releases, is now open. It is estimated that 60 million people will visit it, including 500,000 from overseas. From every corner of the United States millions are expected

to pour in. Great numbers of people coming together act like a huge purse net bringing in any contagious diseases that may exist in the huge areas from which they come. This has been seen in fairs of this kind, in armies, and to a lesser extent in schools and colleges.

We are assured that every precaution has been taken, not only by the authorities of the Fair itself, but also by the health authorities of New York City. The City Department of Health has, in coöperation with the Fair Corporation, established a branch on the Fair grounds under the direction of Dr. John G. Grimley, Special Deputy Commissioner of Health. It is to deal with water supplies, plumbing, foods, milk supplies, the disposal of sewage, communicable diseases, and nuisances in general. Special regulations to strengthen the Sanitary Code of New York City have been passed with the special object of safeguarding the health of the vast influx of visitors. These will be carried out by a staff of 35 thoroughly trained inspectors who will daily visit the 600 eating and drinking establishments on the Fair grounds.

All food handlers are to be examined once a month and cards issued to them. No permit will be issued to any food establishment which does not meet the requirements of the World's Fair Special Sanitary Code as well as the Sanitary Code of the City of New York.

Sanitary regulations require that all glasses, crockery, and utensils used in the serving of food must be properly washed in a solution of soap, soda, or other cleansing powders and treated with a final rinse of hot water at 175° F. for a period of one minute.

Machinery has been devised for the disposal of the enormous amount of garbage which would otherwise accumulate. Specially constructed garbage trucks have been designed and each will be followed by another truck containing two tanks of 1,000 gallon capacity each carrying a cleansing fluid.

Under the Fair Corporation, Dr. J. Peter Hoguet, Medical Director of the Fair, will be in charge of a comprehensive program. Two years of study have been given to the plans and it is felt that persons may come to the Fair with every assurance of protection against disease as well as of care in the event of accident or disease. A staff of 24 doctors and 30 nurses will be in attendance constantly. The Fair personnel of more than 5,000 has been vaccinated against smallpox.

There are 7 first aid stations, each with a waiting room, rooms for the doctors and nurses, and wards for men and women. Serious cases will be hospitalized temporarily on the grounds and transferred by ambulance to outside hospitals as soon as possible. Five air conditioned ambulances will operate on the Fair grounds. There is also a truck carrying a portable X-ray equipment, and a launch with every provision for resuscitation in cases of drowning.

While it is true that these precautions are being taken largely for the benefit of the visitors, it is equally true that all health officers, nurses, inspectors, and, in fact, everyone interested in the health preservation of masses will find much of interest and instruction.

Another interesting question comes up. There are some 250,000 automobile trailers in the United States, and questionnaires indicate that between 10,000 and 12,000 will be brought to New York, many to be occupied by the owners during their visit. Of these, it seems that two-thirds expect to find facilities for parking and living within a short distance of the Fair. It therefore seems desirable that a camp adjacent to New York capable of accommodating 1,200 trailers, provided

with sewerage, baths, lights, etc., be established, since there are no large trailer camps in the vicinity of the city. The matter is engaging the attention of the authorities and the health officers of the counties adjacent to New York are studying the question and preparing to meet it. A conference of the Health Officers of the New York Metropolitan Area was held January 24, 1939, and it was the general opinion that the trailer problem might be a real one. No provision has been made up to the time of writing, but the health officers are awake to the problem and there is little doubt that it will be taken care of efficiently by the time the trailers begin to arrive in numbers.

LETTER TO THE EDITOR

TO THE EDITOR:

As a member of your important Association, I take pleasure in informing you that in collaboration with Dr. David R. Iriarte, I yesterday presented to the National Academy of Medicine an interesting work on Carate, or Mal de Pinto, indicating that for the first time in Venezuela we have found the germ which produces this disease. Its characteristics coincide with the findings of Grau and Triana in Mal de Pinto. It belongs to the Spirochaete family, Genus *treponema* of Noguchi.

The germ causing Carate or Mal de Pinto in Venezuela and Mexico is a *treponema*, very slender, measuring from 15–18 microns in length by 0.20 to 0.25 microns in width, with 12–16 rigid spirals. It has rotating movements around its major axis without propulsion, changing slowly in the dark-field, sometimes taking the form of a circle, sometimes a rod with symmetrical nodes at equal distances. In the blood-lymph obtained by scarification of the affected spots, the blue as well as the red varieties, it lives for more than 3 hours under the microscope.

Carate, according to the observations of Colombians, Mexicans, Cubans, and ourselves, can no longer be regarded as only a repulsive disease, but must now be regarded as among communicable diseases like syphilis and buba (yaws), the serological reactions of Wassermann, Kahn, etc., giving strongly positive results in 100 per cent of all active cases and in 78 per cent of those clinically cured; that is, in those whose spots have disappeared after treatment based on arsenic and liposoluble bismuth preparations.

With the discovery of the *treponema* of Grau and Triana, we believe that all of those diseases called by a variety of names in Central and South America, beginning in Mexico with the name Mal de Pinto and continuing as Cute, Carate, Carare, Catavi, etc., down to Brazil where it is called Puru-Puru, are one and the same.

With this interesting communication concerning Carate in Venezuela, I offer my highest regards.

PUBLIC HEALTH EDUCATION*

What the Visitor Does and Thinks—The American Museum of Health, 30 Rockefeller Plaza, New York, N. Y., is appearing to the public at the New York World's Fair. In that setting is established its initial collection of exhibits, later to be moved to the permanent home of the Museum.

The Museum has received from the Carnegie Corporation of New York a grant for an extensive study of visitor reaction during the Fair. The U. S. Public Health Service is coöperating, with Dr. Derryberry of its staff in charge of the study.

As a result of this investigation, the Museum expects to have data based on objective observations which will serve to guide its exhibit policies in the future. We hope to ascertain for instance what the average level of health information is among the public so that we may have a base on which to plan our future health education efforts.

General direction of the study is under a committee consisting of Dean Dearhorn, of New York University; Dr. Rice, Commissioner of Health, New York City; and Homer N. Calver, Secretary of the Museum. Dr. Livingston Farrand is Chairman of a General Advisory Committee.

When the Western Branch Meets—July 23–28, 1939, in Oakland, Calif., the Western Branch, A.P.H.A., will offer to—

... members who are interested in health education of the public and health education in the schools an outstanding Health Education Symposium which will take place on four separate half-days during the week. Except

for one address by an outstanding guest speaker, there will be no formal papers. The Symposium will be presided over by an authority in the field of health education. The entire group will be divided into two main sections—one devoted to school health education, the other to health education of the public. The school health education group in turn will be divided into at least three divisions—one on classroom teaching, one on school health service, and one on physical education and recreation; each of these divisions to be given ample opportunity for round-table discussion of their particular problems and presided over by an outstanding leader in this field. The group interested in health education of the public will in turn be divided into at least four divisions, each led by an outstanding authority.

Joint Health Committee Reorganized—A reorganization of The Joint Committee on Health Problems in Education of the American Medical Association and the National Education Association is announced in *The Journal of the American Medical Association* for March 25.

The general principles of the reorganized committee include that it shall be constituted of the two associations as a whole and not of any department or section of either one; that it shall include no representatives of other health agencies and shall be strictly a joint committee of the participating organizations; that it shall consist of five representatives of each organization. . . .

The principal objectives of the committee are defined as: (a) to promote a joint understanding between physicians and teachers; (b) to bring to bear on health problems in education the best thoughts in medicine and pedagogy; (c) to identify health problems in education and endeavor to promote constructive solutions for them; (d) to seek publication of the conclusions of the committee through the columns of the periodical publications of the participating organizations whenever possible and to publish pamphlets principally as reprints when special indications for such publication exist.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22nd St., New York, N. Y.

The Mayor's Message to the Aldermen—Attention Caller Ira V. Hiscock sends the text of the annual message of Mayor John W. Murphy to the New Haven Board of Aldermen.

Under "Health," the Mayor said:

Man can have no greater or better asset than good health. Therefore one of the chief and most important obligations imposed upon those in charge of municipal government is to insist that adequately trained persons shall direct the health work of the community, that they work from a sound health plan, and that sufficient funds and trained personnel be provided to make the plan effective.

New Haven has a fine Health Department, a definite health program, and the record of previous years and of the year just past is one of accomplishment and proof of its value to our people.

Then 8 points in the record are listed, and the Mayor continues:

The Health Department has many other activities designed and carried out in the interest of public health. It is a source of satisfaction to know that this is a healthy city in which to live. Therefore, we should cooperate in every way possible with our Health Department in order that conditions here may be maintained and improved.

The Doctor Looks at the Voluntary Health Agency—Under this title a group of important aspects of public health were presented at Kansas City, Public Health Education Section, by Paul A. Teschner, B.S., M.D., Assistant Director, Bureau of Health Education, American Medical Association.

Dr. Teschner said, in part:

The medical profession has always stood, and stands today, in favor of public health work and public health education of the right kind and properly directed by competent experts in their field. Such work is of value to the community in bringing about a betterment of the public health.

It is impossible to give a description of every voluntary health agency in the field. I prefer the word "voluntary" to "private" health agency, because voluntary appears to be a genuinely descriptive term for those organizations, most of which are doing a good job in a field that is not overcrowded. Since they have solicited the public for funds to

accomplish their work, they no longer have a just claim to the term "private."

The physician's conception of a voluntary health agency which he can support is an educational institution; a valuable factor in the dissemination of health knowledge; a pioneering agency breaking new ground; a research organization. This agency cooperates in bringing education to a public in search of health, and works toward greater efficiency in the prevention of disease. The prevention of disease years ago was a matter between the physician and his patient. Today, it is no longer possible for the physician singly to carry out this all-important work. Prevention of disease requires not only physicians, but biologists, laboratory workers, nurses, administrators, educators, etc.

The physician also sees the voluntary agency as a compiler of health facts as well as a disseminator of the knowledge gathered by others. To him, the agency becomes a research body as well as an educational institution. The physician looks at all three groups concerned in the public health in the following way:

1. The practising physician deals with the family and the sick individual in each family.

2. The health officer deals with a group of families—not the single families, but the group called the community. He deals with these individuals in health, not in illness.

3. The voluntary agency adopts both the individual families as well as the community family. Its concern is with special members in each family.

... Large numbers of the public have been educated to the point where it now no longer fears certain illnesses nor expects certain diseases. Rarely do we find an educated individual who expects to die of scarlet fever, typhoid fever or even tuberculosis. Due to the rapidity with which news is disseminated, it now does not require twenty years for news of a medical discovery to be given to the man in the street. The information is given to him almost as rapidly as it is compiled.

Centuries ago, the blind, the crippled and the mentally defective were abandoned to their fate. As man progressed and became more humane, the blind, the crippled and mentally defective were given custodial care which, in most instances, was inferior. Today, efforts are being made toward the prevention of these conditions and toward the rehabilitation of those individuals who suffer from any of the three. No longer is it simply custodial care, but earnest endeavors are made to restore them to as nearly normal as possible. . . .

... Even though the general public, as

exemplified by the man in the street, learns of medical discoveries almost immediately, time is still required for the value of such discoveries to become manifested. The physician wisely refuses to accept without verification the work of any one individual. He chooses to wait until that work has been proved or corroborated by other workers arriving at the same conclusions. When the work has been corroborated, then is time enough for a general acceptance of new discoveries, new methods of treatment or improvements in treatment by the medical profession.

It is here that the voluntary health agency can play its most important part. The agency can, by its special technics, interpret to the public the new discoveries and new methods of treatment for the various disease conditions. Some may hold that this is the job of the official agency. It is impossible for the official agency to go as thoroughly into such problems as can the voluntary health agency. It is impossible for the individual physician to educate the public as thoroughly as can the voluntary health agency. The voluntary agency's field is not treatment. Because of its specialization, the agency is able to do a far better job of interpreting to the public the known factors about a particular disease. By the use of special technics, by the use of funds for research, it can do a job of which the agency as well as the official health agencies and the medical profession can be proud.

For example, the individual physician cannot write to his patient and family and say, "Come in to see me next January if you are crippled from infantile paralysis," "Be sure to visit me next March for heart disease," "For tuberculosis, my office will be open to you in April," and "Come to see me in November about cancer." The voluntary agency can say to all patients of all physicians—"The time to determine whether you are free from heart disease is now," "Now is the time to see if you are safe from tuberculosis."

The agencies serve best in research by developing their special technics and by concentrating their efforts on a single problem. The practising physician and the health official cannot follow in detail all the suggestions made by all the agencies. He must choose from each organization the material that appears to him of greatest importance and usefulness for his practice or community. . . .

... Throughout the years, since the formation of each agency, physicians have supported them in matters that they deemed were in the best interest of the public health. Most of the voluntary agencies had phy-

sicians among their founders and today have physicians on their governing boards. Nevertheless, the physician still reserves the right to disagree with policies and aims which may seem to him contrary to public policy. All the physician asks is that the agencies carry out their purposes as they themselves have stated them in their articles of incorporation or organization. He asks only that the field of treatment be left where it properly belongs—in the hands of the physician trained to do so. The key-note for success for education of the public is coöperation between the medical profession, the official health agencies and the voluntary health agencies.

Instruction of Food Handlers—

Last year plans were made for giving required instruction to all persons handling food in Flint, Mich. Director H. S. Adams, Division of Food and Sanitation, Dept. of Public Health, explains the plan:

To make this instruction period more valuable and educational, a series of pictures were taken in Flint food handling establishments, depicting certain sanitary procedures and measures which are generally conceded to be of value. Two instruction periods are held each week, one on Monday afternoon, and the second on Tuesday evening. At this time a series of 12 slides are shown and an illustrated lecture given. We begin by placing emphasis on good physical health, and make mention of certain diseases that may be transmitted through food. Stress is placed upon the importance of a proper physical examination. Personal hygiene is next discussed, including the importance of personal cleanliness and hand washing, and the significance of wearing clean washable outer garments is stressed.

From personal health and hygiene, we then discuss methods used in food establishments, and pay particular attention to the sterilization of dishes, glassware, and eating utensils. Slides are shown on the proper protection of food products from contamination. Another slide, showing the interior of a modern pasteurization plant, is used, which gives opportunity to stress the importance of pasteurization and the necessity for care in handling dairy products. In conjunction with the subject of milk, a slide is used showing milk being served to a restaurant customer from the original container. In addition to the slides, we have shown a motion picture entitled "Our Common Enemy." This depicted the life cycle of the common house fly and

stressed very well the germ-carrying ability of the fly. This was in line with our food ordinance regulations, requiring that food and food products be protected from the fly nuisance.

Director Adams says further:

We believe that the illustrated lecture for food handlers, conducted routinely, as is the case here, has not been developed to the extent it deserves. We would be very pleased to learn of other departments that are working on a similar plan. From our standpoint, the results of this educational work, over this relatively short period of time, has seemed to have been very worth while.

An Exhibit in New York—Returning to New York after a 2 year 15,000 mile tour of the United States, the famous Transparent Woman, who made her debut at the New York Museum of Science and Industry in August, 1936, began a second appearance February 28 at the Museum in Rockefeller Center. The return engagement was a result of the inquiries about the unique transparent figure which have been received at the Museum ever since it left there early in 1937. An average of 200 persons a week have asked for the exhibit during the past 2 years.

The exhibit, the contribution to public health education of S. H. Camp, of Jackson, Mich., will be on view during the World's Fair, with special lecture demonstrations every hour.

RADIO

Beginning on March 4, the radio health program which has been sponsored since 1932 by the Baltimore City Health Department and the Medical and Chirurgical Faculty of Maryland changed its general nature from a 5 minute talk to a 15 minute health drama. To do this, Station WFBR and certain volunteers from the little theatre groups in the city have assisted in establishing The Baltimore Health Players.

For the 4 Saturday evenings in March a trial was made in dramatizing important "Keeping Well" messages as follows: March 4, "They've Got to Have It" (Measles); March 11, "Murder by Love" (Diphtheria Prevention); March 18, "Milk"; and March 25, "The Scarlet Scourge" (Scarlet Fever).

If the venture proves successful, it is hoped to continue The Baltimore Health Players on successive Saturday evenings at 7:30 o'clock. Topics already selected for these broadcasts include lead poisoning, maternity hygiene, pneumonia, and syphilis.

The Department of Social Welfare and Public Health, American Home Economics Association, has a committee for the Exchange of Radio Scripts. The committee now offers 14 scripts in narrative form, and 22 dialogues, most of which have to do with foods and nutrition. Borrowers pay postage both ways. For a list of scripts, write to: Pauline Murrah, Nutrition Consultant, Dept. of Health, 125 Worth St., New York, N. Y.

For facts about radio ownership and use in rural America, by states and groups of states, see "The Joint Committee Study of Rural Radio Ownership and Use in the United States." Joint Committee on Radio Research, 420 Lexington Ave., New York, N. Y., includes carefully detailed and illustrated description of the study methods.

If one wishes information about short wave educational programs, write to Station WIXAL, University Club, Boston, Mass.

Some topics from Connecticut Dept. of Health, Hartford:

The public more aware of syphilis . . . Investing in community health (public funds for health) . . . Why wait for toothache? . . . Your health and how to protect it . . . The 1939 baby (what is being done for babies).

"Your Child's Health" is the spring

theme for Homemakers Forum Radio Program, broadcast over Station WOR, and short wave via W2XJI, every Thursday, 1:45 P.M. For a program and for single copies of the talks, write to Homemaker Forum, New Jersey College of Agriculture, New Brunswick.

Says *Weekly Bulletin*, City Dept. of Health, Albany, N. Y.:

Tired of the blatant ballyhoo over the radio, a New York physician, Dr. N. Thomas Saxl, writes to the *New York Medical Week*: Why not fight fire with fire? When one listens to the daily radio programs one cannot but be impressed by the fact that a goodly percentage are sponsored by proprietary medical products. The constant repetition of "Physicians prescribe" or "Doctors advise" or "Ask your doctor" is bound ultimately to impress the laity with the veracity of such statements. Would it not be possible for the proper committee of the New York County Medical Society to note these for a period of time and then reply through the medical information bureau in one of our own medical broadcasts that these products do not have the sanction of organized medicine?

MAGAZINE ARTICLES

"Health Committees in Rayon," "Hosiery Workers Join the Anti-Syphilis Crusade," and "Milwaukee Labor Leads Fight for Medical Center" appear in the health section of "Workers' Education through Action," an issue of *Affiliated Schools Scrapbook*, 302 E. 35th St., New York, N. Y. Feb., 1939. 25 cents.

"'Incubator Rooms' Save Premature Babies' Lives." Two pages of pictures. *Life*, 330 E. 22nd St., Chicago, Ill. Mar. 13, 1939. 10 cents.

We have not seen the following, not altogether self-explanatory, topics which have appeared in *Look*, Des Moines, Ia. (10 cents a copy.):

"An Open Letter to American Doctors" (Jan. 17, 1939) . . . "Doctors Fight Back" (Jan. 31) . . . "The Fight on Syphilis" (Feb. 28) . . . "Science Studies Bad Breath" (Mar. 14).

"Why Colleges Are Teaching the Facts of Marriage," by Dr. E. R. Groves (6 pages); "These Are the Charles McMahons: Their Slum Home Is America's Housing Problem" (6 pages—how they live and what it does to them). *Look*. Apr. 25, 1939. 10 cents.

"Miners and Doctors." Editorial. *New Republic*, 40 E. 49 St., New York, N. Y. Mar. 29, 1939. 15 cents. Medical care in 4 coal producing states.

"Doctor, Here's Your Hat." *Publishers Weekly*, 62 W. 45 St., New York, N. Y. Mar. 25, 1939. 15 cents. Describes how Dr. Joseph A. Jerger has been debarred from hospitals because of his writings.

"The Logic of Coöperative Medicine," by M. Shadid. *Social Frontier*, 525 W. 120 St., New York, N. Y. March, 1939. 35 cents. "Coöperative medicine is a compromise between competitive and socialized medicine."

"Take It Easy: Dr. Jacobson Talks with Edith Gates about Relaxation." First things on an important subject. An example of interview form of presentation. *Womans Press*, 600 Lexington Ave., New York, N. Y. April, 1939. 20 cents. See it at any local Y.W.C.A.

REPORTING

"Annual Report" of Chief Medical Officer, New Brunswick, Canada, has a table of contents, that sometimes missing but always commendable feature. Unfortunately it does not mention health education.

A "different" mimeographed report is that issued by Anti-Tuberculosis League, 6101 Arcade Building, Seattle, Wash. Letter size pages; one side each leaf blank; large size cartoon characters on several pages ask significant questions—which are answered. A slightly more opaque paper would have given a better effect, and slip sheeting would have aided.

"Health in 1918 and 1938" is studied in *Birmingham's Health*, County Board of Health, Birmingham, Ala. January, 1939. Use is made of some pictographs. To us these pictorial comparisons should have been twice as large to be effective, with no increase in the size of the lettering, which now rather overshadows the accompanying pictures.

"A Million Vaccinations," and "The Threat to the Western Hemisphere," are two of the chapter headings in "A Review for 1938," Rockefeller Foundation, New York, N. Y.

"New Health Records Established in 1938," a heading in *Michigan Public Health*, State Dept. of Health, Lansing. February, 1939. Includes a high birth rate, and a low death rate.

"Fifty Years of Public Health" in Florida is celebrated in *Florida Health Notes*, State Board of Health, Jacksonville. January-February, 1939. A half page summary by each of the present bureau heads is accompanied by a photograph. Elizabeth Bohnenberger, director, speaks for Division of Health Education.

"The World Is Fairer," is the annual report of Hope Farm, New York, N. Y., a country home and school for dependent children. Title page (second cover page), and map (third page of cover), are imprinted in blue over a light background of farm scenes. Five pages carry a series of small outline sketches and brief paragraphs, each with a milestone bearing the mileage and the date of a highlight in progress of the institution.

Must Know All, Be All, Do All— Applications were invited, by April 20, 1939, by U. S. Civil Service Commission, Washington, D. C., for health education jobs with U. S. Public Health Service. The duties:

Associate Health Education Specialist— With considerable independent responsibility

in relation to a specific subject matter, to plan and execute educational campaigns pertaining to specific diseases, sanitation, and *administrative problems of public health*; to determine the most effective subject matter, form of presentation, media employed, and integration of such campaign with other phases of public health education and the work of other agencies in the same field; to prepare all materials to be used in connection with such educational campaigns, including articles, speeches, pamphlets, folders, bulletins, and other popular publications; to plan application of photographic and art work to layout; to prepare captions; to plan and execute ideas for exhibits for meetings of medical societies, health organizations, etc.; to prepare radio scripts suitable for a public health educational campaign; to prepare scenarios for motion picture, slide film and lantern slide use; to develop photographic and art materials to be used in connection with this program; to act as liaison between the Service and the press, the radio industry, motion picture industry, and other outside groups on matters involving problems of popular health education and the presentation of the scientific work of this Service.

*Assistant Health Education Specialist.—*To read, understand, and interpret highly technical materials of medical, public health, engineering, educational, economic and sociological character pertaining to the program of this Service, and coöperating health and medical agencies; to conduct research studies, investigations and demonstrations relating to the effectiveness of public health educational programs conducted by this Service, State and local health agencies, schools and colleges, and voluntary groups; to assist upon assignment in consultation with State and local health departments and educational authorities and school authorities on public health educational matters; to act as liaison with voluntary agencies coöperating in public health work.

The "Associate" will be paid \$3,200 a year, the "Assistant" will receive \$2,600 a year. Among the requirements:

Applicants for either position must have successfully completed a full 4 year course leading to a bachelor's degree in a college or university of recognized standing.

*Assistant Health Education Specialist—Additional Requirement—*In addition, except for the substitution provided for below, applicants for the position of Assistant Health Education Specialist must show at least 2 years of postgraduate study successfully com-

pleted toward a certificate, diploma, or a degree in Hygiene or Public Health in a college or university of recognized standing.

Substitution of Experience for Postgraduate Education—Applicants for the position of Assistant Health Education Specialist may substitute, year for year, up to a maximum of 2 years, for the prescribed postgraduate study, experience described below under "Associate Health Education Specialist." In any case at least 1 year of such substituted experience must have been in public health work.

Experience—Associate Health Education Specialist—Except for the substitution provided for below, they must show at least 3 years of experience in program building, publications, or public relations work for a recognized educational organization or agency, either governmental or private, an aggregate of 1 year of which experience must have been in public health work.

Substitution of Additional Education for Experience—Applicants may substitute, year for year, up to a maximum of 2 years for the required experience, postgraduate study toward a certificate, diploma, or degree in Hygiene or Public Health successfully completed in a college or university of recognized standing, provided that the 1 year in public health work prescribed under "Experience" above must be shown.

Nonqualifying Experience—Teaching, either adult or juvenile, or clerical or similar office experience will not in itself be regarded as qualifying.

For a full statement, address the Commission, mentioning the job titles, and U. S. Public Health Service.

IN BULLETINS OR JOURNALS

"A Challenge to Nursing Information Committees," by K. F. Young. What

to do to secure the best possible student nurses. *American Journal of Nursing*, 50 W. 50th Street, New York, N. Y. April, 1939. 35 cents.

"Communicable Diseases" is the general topic for the January–March, 1939, issue of *The Commonwealth*, Massachusetts Dept. of Health, Boston.

"Doctor Quiz" heads a column of questions and answers in *Health Briefs*, Tennessee Dept. of Public Health, Nashville. March 15, 1939.

"The Educational Possibilities of the School Lunch," by M. G. McCormick. *Journal of Home Economics*, Mills Building, Washington, D. C. April, 1939. 30 cents. Reprint, 10 cents.

National Negro Health News, U. S. Public Health Service, Washington, D. C., in October–December, 1938, reports on past and coming Negro Health Week and year round health activities.

"The Pharmacist and Public Health." *Health Bulletin*, State Dept. of Health, Richmond, Va. March, 1939. A little considered subject. For both druggist and public health worker.

"Oh, That's How It Is," by Ruth J. Larsen, lecturer on social hygiene. *State Board of Health Bulletin*, Madison, Wis. January–March, 1939. Explains how the title expresses the response of high school girls to real facts.

BOOKS AND REPORTS

Landmarks in Medicine. *Laity Lectures of the New York Academy of Medicine. Introduction by James Alexander Miller, M.D. New York: Appleton-Century, 1939. 347 pp. Price, \$2.00.*

Among the several series of "Laity Lectures" collected in volumes by the New York Academy of Medicine, this will rank among the best. It is largely historical, some of the individual lectures being entirely so, but all of them have their application to present-day problems and interests. A number of texts may be found in this latest volume which are peculiarly apt at this moment when laymen are criticising the medical profession and taking steps to interfere with the good work it is doing. For example, it is pointed out that 500 years ago the average life expectancy was only 8 years, while now it is at least 50 years more and that this marked betterment has come through the efforts of medical science which "has become perhaps the strongest force acting toward human betterment in modern civilization"; and that this modern civilization itself is built largely upon medicine.

The lecture, "Dr. Watson and Mr. Holmes," is of great interest as well as practical. It is safe to say that not many doctors know what the up-to-date coroner and the medical examiner go through in the study of crime as well as of sudden death from any cause.

Among other notable lectures is that by Raymond Pearl on "The Search for Longevity." The conclusion reached is that the "length of life is generally in inverse proportion of the rate of living." The story of more than 2,000 nonagenarians and centenarians re-

vealed that the "vast majority of these extremely longevous folk were of a placid temperament, not given to worry."

The lecture by Dr. Reginald Burbank, on Medicine and the Progress of Civilization, is a well done history of medicine, which unfortunately contains one very incomplete and erroneous statement. He says Sternberg, Laveran and Munson (sic) made it possible to eradicate malaria. Laveran was the discoverer of the malarial parasite. Sternberg introduced Laveran's findings to the profession in America. Munson, evidently intended for Manson (Sir Patrick Manson) outlined theoretically the mosquito transmission of malaria, but Ross, to whom we owe more than any other single man in this respect, with the exception of Laveran, is not even mentioned.

The book ends with an excellent chapter on X-ray by Dr. Cole, a pioneer who has constantly done much to develop the application of X-ray to diagnosis.

All the lectures here collected are excellent, and the selection of a few for special mention is no disparagement to the authors of the others. It is hard to praise the collection too highly. The printing and make-up are excellent.

MAZŮCK P. RAVENEL

The New Food, Drug, and Cosmetic Legislation. *Law and Contemporary Problems. School of Law, Duke University, Durham, N. C. Winter, 1939. 182 pp. Price, \$.75.*

State and local health officials who are concerned with the preparation or the administration of food, drug, and cosmetic legislation will find much

practical and interesting information in this bulletin. In nine articles by as many authorities there are presented excellent analyses and discussions of the new federal laws on these subjects, together with an outline of state legislation pertaining to food, drugs, and cosmetics. While some of the material is conjectural, particularly with reference to the future legal status of these acts, all of it will be of value to the student of these important problems. Here is a veritable textbook at the cost of a magazine. JAMES A. TOBEY

Annual Report of the Public Health Commissioner with the Government of India for 1936—*Government of India Press, New Delhi*, 1938. 353 pp. Vol. I with appendices.

This exhaustive report deals with both the treatment and prevention of disease in India. Descriptive material is well illustrated by charts and maps. Data are presented to show for the population of British India (282 million) a density per square mile of 321, a birth rate of 35, a death rate of 23, and an infant-mortality rate of 162. There is noted a decrease in mortality from smallpox, plague, and cholera. The number of primary vaccinations against smallpox performed (11,047,662) has increased steadily but still only reaches about half of the infants. Under preventive medicine, emphasis is given to the necessity for raising the standard of living of the Indian people, schemes of rural reconstruction being given special attention. One section is devoted to the work of research institutions including the All-India Institute of Hygiene and Public Health, and the School of Tropical Medicine.

IRA V. HISCOCK

Adventures in Living: New Ways for Old—By Thomas D. Wood, M.D., Marion O. Lerrigo, Ph.D., and Nina B.

Lamkin, A.M. New York: Thomas Nelson & Sons, 1938. 320 pp. Price, \$.88.

New Ways for Old is the sixth in a series with the general title "Adventures in Living." The authors in their preface addressed to the teacher set forth the following sound objectives as guiding principles for the whole series:

To teach health as a means to accomplishment and not as an end in itself.

To emphasize happy, healthful living, rather than the details of techniques.

To promote the growth of the whole child by activities which give him real experiences in healthful living.

To create in the mind of the child an attitude of respect for the body and its processes, and to teach about the body as a whole, rather than as a collection of anatomical systems.

To provide for healthful experiences without making the child introspectively health-conscious.

To suggest individual and coöperative projects of social value, utilizing school, home, and community experiences.

To integrate health education with other school subjects and activities.

It would seem that these aims have been pretty successfully carried out in the making of the book under review. The subjects usually included in all such school texts are here but are discussed in a rather unusual and interesting way. The attempt is made (indirectly of course) to suggest incentives for the practice of health habits—as, for example, in the unit entitled "Your Social Life." Incidentally, would not life on this footstool be transformed if some sure-fire way were discovered to teach children how to control their emotions and to enjoy the process of health habit formation?

The device of comparing school life of the early days of this country with our modern ways adds to the interest of this book. The illustrations are simple but to the point. There is a glossary and the index seems adequate.

MERRILL E. CHAMPION

The Social Work Year Book—1939—Fifth Issue—*Edited by Russell K. Kurze. New York: Russell Sage Foundation, 1939. 730 pp. Price, \$3.50.*

An anticipated and necessary addition to the reference shelf, the Fifth Issue of the 1939 Social Work Year Book promises to be even more helpful than its very useful predecessors.

Eighty-two topical articles by distinguished and knowledgeable contributors comprise Part I and provide authoritative information on welfare activities conducted on a national scale.

Part II is a state-by-state account of social work under governmental auspices.

Part III is the familiar and comprehensive Directories of Agencies in social work and related fields, national and state, public and private.

Much of the information presented in the *Social Work Year Book* is unavailable elsewhere and is nowhere available so conveniently and in such organized fashion. W. R. WALSH

The Truth About Childbirth—*By Anthony M. Ludovici. New York: Dutton, 1938. 294 pp. Price, \$2.50.*

"Lay Light on Maternal Morbidity and Mortality," the subtitle to this challenging volume, does not give a sufficient hint as to what follows. In brief the author claims that childbirth should be a normal physiological process. To this statement he will have general assent, but when he affirms that it should be not only a painless affair, moreover, a pleasurable experience, even without anaesthetics or analgesics, he is placing himself in a vulnerable position. His assertion that maternal morbidity and mortality can be reduced considerably may be accepted if we could secure the application of skilled obstetric, nursing, and hospital technics to all mothers regardless of economic circumstances.

Mr. Ludovici blames "the flight from motherhood" largely on feminism, economic conditions, and what he calls "pornocracy" *i.e.*, a state of society in which exhibitionism, smartness at all costs, cars, wireless sets, and any number of amusements without which our happier ancestors did perfectly well, are preferred before natural, simple, and satisfying pleasures for health is the first prerequisite. His solution of our present predicament would be more marriages at earlier ages, more children per marriage, hygienic living, and less meddlesome obstetrics.

It would be an injustice to the author if we did not recognize that an extensive amount of research into the socio-economic and medico-hygienic aspects of the subject had gone into the making of this book. It is thoroughly documented with references and explanatory notes. Whether we agree or disagree with the author's conclusions we will be instructed by the novel material he has introduced. It will be a stimulating but provoking book, especially to the medical profession and to ultra-modern women.

RICHARD A. BOLT

Classic Descriptions of Disease, With Biographical Sketches of the Authors—*By Ralph H. Major, M.D. Springfield, Ill.: Charles C. Thomas, 1939. 727 pp. Price, \$5.50.*

The first edition of this book appeared in 1932 and was widely welcomed. It has made available for students who do not have access to great libraries and who do not know languages most of the epoch-making discoveries in this field of medicine. The second edition has been revised and the author has taken cognizance of certain errors and omissions, some of which were pointed out by friends and those who were interested in the plan and object of the book.

The second edition includes new sec-

tions covering malaria and yellow fever. A number of the biographical sketches have been rewritten and the index has been revised and enlarged. It now contains 403 selections from the epoch-making accounts of disease of 190 pioneer authorities.

It is hard to speak too highly of the value of this book. Each selection given is "either the first known, one of the earliest, or one of the most interesting accounts of the disease in question." The selection has been done with the judgment which comes of a wide study of the classics of medical literature, by one who has an intimate knowledge of the languages involved, so much so that most of the translations have been made by the author personally. He tells in the Preface of the First Edition that Dr. Osler stressed the value of advising students to study classic accounts of disease.

At present when we are perhaps too much given to rushing after new things, it is to be hoped that such books as this will be made required reading in all medical schools. Particularly valuable to the student are the short biographical sketches of those from whose accounts selections are here given.

There are 137 illustrations, many of them being portraits, which are both interesting and valuable. The printing and make-up are typical of the fine work of the publishing house from which it comes. The book can be unreservedly recommended to all libraries, medical or otherwise, and to all who are interested in the history of medicine.

Mazÿck P. RAVENEL

Public Welfare in Transition: Annual Report—By William Hodson, Commissioner. New York: Department of Public Welfare of the City of New York (902 Broadway), 1937. 132 pp.

Elimination of relief for able-bodied

men and women through adjustments in our social and industrial systems, wider and more adequate social insurance coverage to reduce further the nation's home relief rolls, and a flexible relief program for the residual caseload of unemployables that can be contracted or expanded as needs indicate, are urged in the 1937 annual report of the New York City Department of Welfare.

In December, 1937, New York State had a total of 102,926 needy persons over 65 years of age receiving Old Age Assistance. This means that out of every 1,000 individuals 65 years and over in New York State, 133 received this kind of aid. Thirty-eight states had a larger number of recipients per 1,000 than New York.

At the end of the year 10,258 veteran families, comprising over 35,000 individuals were under the department's care. The cost of veteran relief for the year exceeded \$4,000,000. Eighty-five per cent of the Veterans' Division staff are ex-service men. Approximately 4,000 employable veteran recipients were given WPA employment during the year. Improvements in aid to needy veterans included a more elastic budget, medical and nursing services, prescription allowances, dental and optical treatment, housekeeping service in emergencies, and other aid, as needed. The Division of Blind Assistance was formed in May, 1937, to administer financial aid to eligible blind persons in accordance with the revised State Public Welfare Law and Federal Social Security Act. Prior to 1937, assistance was given to the "Poor Adult Blind" in semi-annual installments under the provisions of the Charter of the Greater City of New York. The principal changes under the new law are: assistance is issued on a monthly basis; the budget is based upon actual minimum requirements; eligibility for assistance is more carefully determined; consideration is given to the special

needs incident to blindness. Increased allowance enables the recipient to sustain himself without street begging or supplementation from other agencies, Mr. Hodson points out, and the recipient is able to plan his expenditures to better advantage with payments made each month instead of semi-annually. A total of \$183,768 was expended for Blind Aid last year.

At the end of the year there were 22,692 destitute, neglected, or abandoned children under the care of the Children's Division of the department. Home relief has tended to reduce the number of children who had to be cared for by the department in boarding houses and institutions. The department expended approximately \$27,000,000 during 1937, of which \$15,025,000 were city funds, \$6,280,000 were federal funds and \$5,695,000 were state funds.

IRA V. HISCOCK

Emotional Hygiene: The Art of Understanding—By *Camilla M. Anderson, M.D.* Philadelphia: Lippincott, 1937. 242 pp. Price, \$2.00.

This is one of the finer examples of popular treatment of mental hygiene that professional writers on the subject have turned out in increasing quantity in recent years. As such it will play a useful part in the growing importance of public education in the principles and practices of mental health as visualized by those engaged in organized work in this segment of the public health movement. The author has turned to good account her valuable experience as Secretary of the Pennsylvania Mental Hygiene Committee, and as a psychiatric teacher in the field of nursing education, in bringing the complexities and ramifications of the subject down to the level of understanding of the "man in the street." Indeed, she has done it "almost too well" in that she has over-simplified some of the theories and concepts of the

"new psychologies" upon which mental hygiene is based, and perhaps exaggerated their therapeutic and preventive values, but this is a minor criticism to make of what is, on the whole, a sound exposition of its fundamentals as generally accepted and taught by present-day psychiatry, and presented in an unusually attractive and readable fashion.

Significantly, the title of the book emphasizes the primacy of the emotions as against the intellect in determining healthy mental adjustment and personality development, as conceived by modern students of human behavior oriented to the philosophy and outlook of twentieth century mental medicine and hygiene. The critical reader may find fault with some of the spiritual interpretations of human nature, as the author develops them in the light of Freudian psychology and where they conflict with more orthodox and traditional theological and moral concepts, but, discounting these and after applying his own correctives, such a reader will agree with the general tenor of her discussions and will accept her teachings as having great practical value in the everyday task of the everyday man in better understanding and dealing with his fellow man.

PAUL O. KOMORA

City Hangs Up Eight New Health Records: 1938 Annual Report from the Health Commissioner of New York to the Mayor. *Issued for release in newspapers under date of January 1, 1939.*

The introductory paragraphs of this news release summarize the outstanding features in Commissioner Rice's annual report. There follow extensive tables of statistics on the major causes of death, in which the rates for 1938 are compared with those for the last 8 years.

The whole article furnishes support

to Dr. Rice's assurance to contemplated visitors at the 1939 New York World's Fair "that everything has been done to make their stay in New York City safe from the health standpoint."

For an estimated population of 7,491,790 the general death rate of 9.8 per 1,000 recorded in 1938 is the lowest in the city's history. The reports on specific diseases indicate a similar substantial reduction in the death rates from accidents, tuberculosis, pneumonia, typhoid fever, and diphtheria, resulting in the lowest figures ever registered in the city. The infant and maternal mortality rates are also so low as to constitute a record achievement.

The Commissioner attributes the continued high rates of death from the degenerative diseases to the city's aging population. However, the specific death rates in the higher age groups for diabetes, cancer, and diseases of the heart and arteries do show a decrease. The decline in the city's birth rate has continued.

A tribute to the fine leadership of Mayor LaGuardia is tendered for his aid in advancing the establishment of the district health center program. The coöperation of the newspapers is also acknowledged for their excellent work in publicizing the venereal disease campaign.

Explanatory paragraphs accompany the statistical section which concludes the report. The tables are preceded by the general statement that health conditions were exceptionally good, with no epidemics, major catastrophies, or unfavorable weather conditions in evidence.

IRA V. HISCOCK

Educational Broadcasting—1937
—C. S. Marsh, Editor. Chicago: University of Chicago Press, 1938. 405 pp. Price, \$3.00.

This is a report of the Second National Conference on Educational Broadcasting held in Chicago, November 29–

December 1, 1937, the report being published October 25, 1938.

Health broadcasting is not mentioned, except when Douglas Griesemer, American National Red Cross, in a discussion reminded the audience that numerous health and welfare agencies have had considerable experience in the educational use of radio.

Notwithstanding the fact that the American Public Health Association is listed as one of the sponsors, and several national health agencies appear as coöperating groups, neither radio educational leaders nor the national adult education groups have been really conscious of health education.

This situation emphasizes the importance of the book, which offers a wealth of ideas and information on broadcasting as an educational medium, and the complications growing out of the peculiar nature of radio as a business. We need some far-sighted health people, informed and willing to participate in the broad development of broadcasting as an educational medium. This volume provides much valuable background material.

Of especial interest are chapters on "Talks Programs" (the one chapter giving something on technics), "What Happens to the Listener," "Radio and the Child's Education," "Classroom Use of Radio," and "Symposium of Listeners."

EVART G. ROUTZAHN

The Life of Chevalier Jackson: An Autobiography. New York: Macmillan, 1939. 229 pp. Price, \$3.50.

This autobiography is not only a human document of rare interest but also the story of remarkable achievement in a new field which has brought much relief from suffering and saved the lives of thousands, mostly children. It is the story of a man who was a frail child, living under conditions not con-

ductive to high mental or physical development, and handicapped by poverty. A devotion to his parents and a natural bent for mechanics were the two great interests in his life. "An innate and insatiable urge to make things" possessed him from early childhood throughout his life. He had a struggle to get his education and for some time made his own way as a decorator of china and glass, sometimes as a book agent, and again as a member of the crew of a Gloucester fishing schooner. He finally saved enough money to go to London "the cradle of laryngology" and get postgraduate work in laryngology under Sir Morrell Mackenzie.

His practice, which began in Pittsburgh, was among the very poor, but he soon acquired a reputation for skill in diseases of the upper air passages, the beginning of his world-wide fame in esophagoscopy and bronchoscopy. He developed in 1890 his first esophagoscope which he perfected 12 years later by adapting a light such as was in use on the cystoscope. This enabled him to see into the esophagus and soon he had brought to him many children suffering from stricture due to swallowing lye. He was so impressed by the frequency of these accidents that he devoted much of his energy to laws requiring proper labeling of such dangerous poisons, and to him more than any other person is due the law passed in 1927 requiring poison and antidote labels to be put on each such container.

After some years Jackson evolved the bronchoscope which will always bear his name, and it was perfected year by year. Before his invention the mortality among those into whose bronchi and lungs foreign bodies found their way was 98 per cent; now 98 per cent survive. It must be remembered that Jackson has a marvelous skill in operation, being ambidextrous, in addition to his mechanical genius, but fortu-

nately he is as apt in teaching as in operating, so there are now an imposing number of skilled men in this country who have come under his influence who are doing excellent work with the aid of his instruments.

The book contains 8 pages of photographs of foreign bodies—jackstones, safety pins, tacks, staples, buttons, etc., and even false teeth—removed from patients, chiefly children. The legend on each page urges prevention of such accidents.

The book itself is an outstanding example of the printer's art. Issued in May, 1938, there have been already three reprintings. Many beautiful illustrations in color by the author show him to be a master of the pencil, brush, palette knife, dry point, and colored chalk. There are also a number of photographs. Dr. Jackson has received honors from every part of the world. His book deserves to be read widely and to find a place in private as well as public libraries, medical and lay

MAZÛCK P. RAVENEL

Health Education by Isotype—
By Otto Neurath, Ph.D., and H. E. Kleinschmidt, M.D. New York: American Public Health Association, 1939. 32 pp. Price, \$.25.

Almost every one of us, at one time or another, has had a health story to tell. Usually, when inspiration seizes us, we rush into print—or into display—hustling to get the job done while our ideas are still in their first state of white heat. Far too often the results are eloquent of the frenzied rush. If there is one thing that this pamphlet makes crystal clear, it is that reflection, planning, analysis, and critical appraisal are all essential in telling a health story.

Health Education by Isotype is a persuasive plea for the use of this visual language in interpreting health to young and old, to the erudite and to the

uneducated. Isotype is not offered as ready means for the mechanical translation of any health idea into pictures. Instead, it is suggested as a valuable medium through which the educator, working jointly with the specialist in the method, can often reveal social facts most effectively.

Varied uses of Isotype in text illustrations, as lecture aids, for classroom use, in slides and motion pictures, as well as for exhibits, are discussed briefly.

Every public health worker—administrator, engineer, nurse, as well as educator—will profit by exposing himself to this Isotype infection, for it tends to make one immune to that common ailment, “rush of brains to the head.” To them all we commend this pamphlet. Its publication has been made possible through the generosity of the Carnegie Corporation of New York to which the American Public Health Association makes grateful acknowledgment. RAYMOND S. PATTERSON

Nutrition: The Newer Diagnostic Methods. *Proceedings of the Round Table on Nutrition and Public Health—Sixteenth Annual Conference of the Milbank Memorial Fund, March 29–31, 1938. New York: Milbank Memorial Fund, 1938. 192 pp. Price, \$1.00.*

This volume sets forth the proceedings of the 16th annual conference of the Milbank Memorial Fund. One round table was devoted entirely to nutrition and its relation to public health. Impaired nutrition among the general population is sufficiently exten-

sive to make it a matter of concern to public health agencies. Means must be devised to detect nutritional deficiencies long before they produce their most obvious characteristics. Work needs to be done in determining the constituents of optimal nutrition and means provided for their attainment by the average individual.

To these ends discussions were held on various methods for detecting early nutritional defects. Dr. T. Wingate Todd opened the discussion on the use of roentgenology. Drs. Hecht and Feldman presented the use of the dark adaptation test in detecting avitaminosis A. The detection of early vitamin B₁ deficiency by the use of the electrocardiograph and of specific color tests was discussed by Dr. Weiss and by Drs. Levine and Marples respectively. Dr. Spies covered the subject of nicotinic acid and its relationship to pellagra while Drs. Farmer and Abt discussed the utility of plasma ascorbic acid tests for latent avitaminosis C.

The detection of nutritional anemia by hematologic methods was presented by Dr. Guest. Dr. Youmans opened the discussion on the use of plasma protein determinations in the diagnosis of edema of nutritional origin.

The tables, graphs, and illustrations as well as the supplementary informal discussions, add greatly to the value of the record. The correlation of the experiences of different investigators in a conference of this type not only serves to promote scientific advance as a whole but their record will serve to inform and stimulate others.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Montgomery County (Md.) Steps Out—Do you know what "the adjustment of the total personality" means? Even if you do, you will still find much of interest in this account of a year's experience with a county-wide psychiatric service. If you don't the article will prove practically a new department in your little store of knowledge.

ANON. Psychiatric Service in a County. Health Officer. 3, 10:287 (Feb.), 1939.

130,215,000 Souls—This is the population of the continental United States on July 1, 1938, as estimated by the Bureau of the Census. It is based on births, deaths, and excess of immigration over emigration. Tables are given showing estimated population annually since the 1930 census, and by states.

ANON. Estimated Population of Continental United States and Outlying Territories and Possessions July 1, 1938. Pub. Health Rep. 54, 5:180 (Feb. 3), 1939.

Life Expectancy Rate Up—Most of us assume that the actual average age at death is the same thing as life expectancy at birth. This is not likely to be true, for the expectation of life is based upon a hypothetical group subject to the same age specific rates throughout life. This is made clear in a brief note quoting Dr. Dublin's estimation of a life expectancy rate of 62.0 for last year.

ANON. Estimated Life Expectancy for the United States, 1938. Pub. Health Rep. 54, 8:311 (Feb. 24), 1939.

Slaughter House By-Products—It is a great comfort to know the derivation of the word "catgut." It is not what you think, but is supposed

to have come from kit-gut, a kit being a small violin. The sanitary features concerned in the various processes of making sausage casings, etc., also make the paper an interesting one.

AUSTIN, J. The Hygienic Treatment and Disposal of Offal and By-Products in Abattoirs. J. Roy. San. Inst. 59, 9:622 (Mar.), 1939.

Health Facilities' Study—Available clinic services depend upon the size of the community. In counties predominantly, rural health programs are seriously handicapped by the absence of clinics so necessary in completing the health educational activities of the health agencies. This is the finding of an extensive survey of counties.

BOROWSKI, A. J., and PLUMLEY, M. L. Preventive Clinic Facilities Available in Ninety-four Selected Counties of the United States. Pub. Health Rep. 54, 9:335 (Mar. 3), 1939.

Anent Spiritual Vitamins—In this revealing dissertation on mental hygiene addressed to the informed layman there is much of immediate value to all health workers. Personality, we are told, derives from *persona*, the mask put on by the ancient actor. In mental disorders, the mask is broken and we see revealed in all their repulsiveness the processes of human nature. What this means in our attitudes toward public mental health administration is made clear. The desire to quote here from the many brilliant passages is almost irresistible.

CAMPBELL, C. M. Human Needs and Social Resources. Sci. Month. 48, 4:293 (Apr.), 1939.

The Physical Jerks and Public Health—One gets the impression from this British discussion that if indi-

viduals will only do something about maintaining physical fitness, then the level of public health will be raised. Health education is approved and urged as a public project. In the ensuing discussion favorable mention is made of the periodic medical examination that is "in force in parts of the U. S. A."

EDWARDS, T. P. Physical Fitness in Relation to Public Health. *J. Roy. San. Inst.* 59, 8:573 (Feb.), 1939.

Con Versus Pro in Social Medicine—Two able articles, one pointing out the dangers of the proposed national health scheme, and the other, the need for a method of providing adequate medical care, are presented. The editors should be widely commended for this eminently fair airing of both sides, a procedure which is all too infrequently practiced in this land of the free and the home of the brave.

FISHBEIN, M. American Medicine and the National Health Program, and

PETERS, J. J. Medicine and the Public. *New Eng. J. Med.* 220, 12:495 (Mar. 23), 1939.

School Attendance by Contacts—British views on the exclusion from school of communicable disease contacts. The author wishes the rigorous regulations to be changed to allow measles, German measles, and chicken pox contacts to go to school, and the return of scarlet fever and diphtheria home contacts one week after the isolation of the case.

FORBES, D. School Exclusion in Infectious Disease. *J. Roy. San. Inst.* 59, 8:559 (Feb.), 1939. (See also) Terminal Disinfection and Exclusion from School. *Pub. Health.* 52, 5:133 (Feb.), 1939.

For All Health Propagandists to Read—Here is good straightforward reporting upon experience with the health examination. The author urges others to make use of it, even though he concludes that it cannot be of great immediate importance to preventive

medicine because we still know so little about the mode of origin of so many diseases.

FRITZ, R. The Periodic Health Examination as a Method of Clinical Investigation. *J.A.M.A.* 112, 12:1116 (Mar. 25), 1939.

Where Relaxed Vigilance Takes Its Tragic Toll—Reporting upon 470 water-borne disease outbreaks in the United States and Canada over a 16 year period, the conclusion is reached that the data presented do not indicate any inherent weaknesses in operating methods of water treatment plants, but rather that accepted methods are not always followed. Too much faith often is placed in a limited number of water tests. More attention should be given to sources of pollution, and to an ample factor of safety in plant operation. Needed research also is listed in this comprehensive study.

GORMAN, A. E., and WOLMAN, A. Water-Borne Outbreaks in the United States and Canada, and Their Significance. *J. Am. Waterworks Assoc.* 31, 2:225 (Feb.), 1935.

Doctors, Nurses, and Deliveries—In two rural counties in the South, a health department nursing service has done much to improve maternal health through successful home deliveries. Experience shows that this service has not detracted from the effectiveness of the generalized health department nursing program.

LAPHAM, M. E. Coöperative Obstetric Delivery Service by Private Physicians and County Health Departments. *South M. J.* 32, 2:191 (Feb.), 1939.

Finding Operable Cancer—Stomach, colon, and breast are the frequent sites of cancer. Extirpation is not performed in more than half the cases because they are hopeless, but surgeons are now discovering a larger proportion of operable cancers, because the medical profession is beginning to discard textbook signs supposed to be pathognomonic of

cancer (there are none of early cancer).

MACCARTY, W. C. A Hopeful Factor in the Cancer Problem. *Am. J. Cancer.* 35, 2:275 (Feb.), 1939.

Pertussis Vaccine Protects—Another successful experience with vaccine in the prevention of whooping cough. In the test group the communicability rate was 28 per cent, whereas it was 85 per cent in the control group.

MILLER, J. J., and FABER, H. K. Immunization Against Pertussis. *J.A.M.A.* 112, 12:1145 (Mar. 25), 1939.

Bending the Twig—Curious-minded sanitarians will find much of interest in this series of papers about the purposes of the Bureau of Child Guidance in the New York City schools; the difficulties inherent in a program involving two professions; and diverse administrative problems together with their solutions. A little knowledge about what others are doing never did anyone much harm.

O'BRIEN, F. J., *et al.* The Bureau of Child Guidance, Board of Education, City of New York (and five related papers). *Understanding the Child.* 7. 4:3 (Jan.), 1939.

Where to Hunt T.B. Cases—Tuberculosis case finding is most productive when directed to the examination of contacts and referred suspected patients, or group of examinations in certain industries and adults generally in the lower economic strata. These two types of services are of more importance than the routine examination of school children. Experience in New York State confirms this opinion, which will bring no comfort to summer campers or the open air school marms.

PLUNKETT, R. E. Case-Finding. *Am. Rev. Tuberc.* 39, 2:256 (Feb.), 1939.

Which Toxoid?—Animal experiments are reported which indicate that one dose of toxoid-alum precipitate equals three doses of unmodified toxoid.

A high degree of immunity results from one dose of toxoid-alum precipitate followed 2 weeks later with one of unmodified toxoid, and the antitoxic titer can be enhanced by another dose of unmodified toxoid at the end of a year.

POVITZKY, O. R. A Comparison of Antitoxic Response and Persistence of Antitoxin in the Blood of Guinea Pigs Injected with Different Preparations of Diphtheria Toxoid. *Am. J. Hyg.* 29, 2:89 (Mar.), 1939.

Stamping Out Syphilis—Health officials and others bent on drawing up laws for the control of syphilis will do well to read all the evidence here presented which suggests the unwisdom of attempting to cover all the medical exigencies. The simpler, the better, evidently.

STOKES, J. H., and INGRAHAM, N. R. Syphilis and the Law. *J.A.M.A.* 112, 12:1133 (Mar. 25), 1939.

Mouth Lesions and Dietary Deficiencies—*Macacus rhesus* monkeys, whose dental formula is similar to man's and who require both vitamin C and nicotinic acid, as does man, were tested with vitamin deficient meals. Varying manifestations of gingivitis and stomatitis (in one study), and (in the other) necrosis of the periodontal tissues, followed the feeding of vitamin deficient diets. Control animals had healthy mouths. One may assume that none of the monkeys brushed his teeth twice a day or saw his dentist twice a year.

TOPPING, N. H., and FRASER, H. F. Mouth Lesions Associated with Dietary Deficiencies in Monkeys, and

TOMLINSON, T. H., JR. Oral Pathology in Monkeys in Various Experimental Dietary Deficiencies. *Pub. Health Rep.* 54, 11:416 (Mar. 17), 1939.

It Can Be Done—Practical methods for the removal of dangerous dusts are described in this article which fixes 10 million particles per cu. ft. as the safe upper limit of dustiness. The illustrations are good, too.

URBAN, E. C. J. Ventilation in the Granite Industry. *J. Indus. Hyg. & Toxicol.* 21, 3:57 (Mar.), 1939.

Franklin the Hygienist—The health worker who isn't delighted with the story of "Dr." Franklin's excursions into the fields of medicine and hygiene, must be a crusty old work horse indeed. During his eighty-one years, the redoubtable Benjamin certainly did his share of philosophizing.

WRIGHT, R. D. "Dr." Franklin. *Health Officer.* 3, 10:308 (Feb.), 1939.

Questionable Biologic Concept Bites Dust—Collapse therapy results

indicate that there is but little, if any, difference between whites and negroes in natural resistance to tuberculosis, and physical habitus appears to play no part in the different illness rates. When we, the people, decide that it will pay to provide adequate isolation for colored cases and allow better general living conditions for this population, then death rates among the colored will repeat the experience of the white race. A lot more hygienic hooey is disproved in this excellent paper.

WILLIAMS, G. D., and APPLEWHITE, J. D. Tuberculosis in the Negroes of Georgia. *Am. J. Hyg.* 29, 2:61 (Mar.), 1939.

"The Golden Triangle" and the "Point." The junction of the Allegheny and Monongahela Rivers to form the Ohio

PITTSBURGH EXPECTS YOU IN OCTOBER

CITIES have their own personalities, even as you and I.

Some are short, bustling individuals, always on the jump. Others are lean, white-haired men, fond of their firesides and slippers.

But the personality of Pittsburgh—"Vulcan's Workshop"—is the strength of enormous industry, the energy of coal and fire, and the vigorous pulse of great water, rail, and air transportation systems.

Pittsburgh is the birthplace of air hygiene. And the district, in which heavy industry predominates, is notable for its constructive activities in improving industrial health conditions.

Yet with all that, there is still a greater personality—a personality with culture and refinement deeply rooted in a high regard for civic duty and social responsibility.

Away from its busy terminals, its factories and stores, is the Pittsburgh of intellectual and artistic achievement, that social inner-existence of the city,

made possible by municipal statesmanship.

The Civic Center of Pittsburgh has achieved international renown. Its Schenley Park, comprising 383 acres, is one of the world's finest. It was donated to the city by Mrs. Mary E. Schenley of London, England.

The Civic area forms a modern Acropolis—a city within a city—with stately cathedrals, shrines, colleges, laboratories, museums, libraries, homes, hotels, memorials, and recreation and sport pavilions, representing an investment of more than a half billion dollars.

Convention delegates will have every opportunity to visit the gigantic modern workshops of heavy industry, as well as the cultural centers of Pittsburgh.

You will see Phipps Conservatory with its 125,000 species of flowers; the famous Andrew Carnegie Museum, the Carnegie Library of a million volumes; the Carnegie Art Galleries, where the

world's only International Art show is an annual feature and which will be in progress during the Association's meeting, the Carnegie Music Hall, the Mellon Institute, Heinz Memorial Chapel, Syria Mosque, which has the largest Shrine membership in the World; the Cathedral of Learning of the University of Pittsburgh, rising 542 feet into the air, the tallest skyscraper schoolhouse in the world; the terraced campus of Carnegie Institute of Technology; and the memorial to Stephen Collins Foster, composer of "Old Folks at Home" and "Old Black Joe."

Pittsburgh is not just another city. It is the heart of Allegheny County, the hub of an industrial empire, which supplies the wheels, power, generators and turbines to keep America and the rest of the world on the move, and to provide the structural materials for the "framework" of other cities. The steel for the Trylon and Perisphere of the World of Tomorrow in New York was made in Pittsburgh. Whatever the world needs from heavy industry, Pittsburgh can produce.

Pittsburgh and Allegheny County cover 21,103,980,000 feet of earth, on which live and work nearly 2,000,000 people. Last year the 2,000 manufacturing plants of the city and county shipped—over five railroads and three rivers—162 million tons of materials valued at a half billion dollars. This tonnage was 25 times that which passed through the Panama Canal in the same year.

In the county are 4,000 farms, valued at \$33,000,000, whose products last year sold for \$7,000,000. Our steel, iron, coal, aluminum, glass, food, electrical and other supplies of all kinds have been placed on markets in all parts of the world.

Pittsburgh produces the steel for skyscrapers, bridges, houses, highways, ships and hair curlers, just as examples of the more than 5,000 uses to which

The Heinz Memorial Chapel of the University of Pittsburgh

this indispensable metal has been applied. The aluminum pots and pans in which your food is cooked come from Pittsburgh, and Heinz food specialties are found on millions of tables.

Pittsburgh fabricates aluminum and steel for streamline trains. It furnishes the steel rails, locomotive parts, the air brakes and generators which make the trains move over the large railroad network from the Atlantic to the Pacific Coast and throughout the world.

And Pittsburgh supplies much of the steel and most of the safety glass which go into the annual production of more than 4,000,000 automobiles. The famous Westinghouse Electric and Manufacturing Company, whose founder developed the use of alternating electric current, manufactured the recently installed huge electrical apparatus for the generation of power and the furnishing of a water supply to Pacific Coast cities from Boulder Dam.

Likewise, the contributions of Pitts-

World's Tallest Educational Building. The University of Pittsburgh's "Cathedral of Learning," 42 story Gothic structure which houses the undergraduates' schools, School of Law, Bureau of Business Research, Research Bureau for Retail Training, Graduate School, libraries, classrooms, and offices. Twenty-two other buildings on the campus house the professional and technical schools

burgh men and women in the conservation of health, and in medical and biological research, have been outstanding.

In Pittsburgh are located 38 hospitals. Within the metropolitan limits 1,800 physicians and surgeons minister to the needs of the community.

As an example of teamwork between medical science and heavy industry, surgeons found some months ago that a new form of stainless steel can be used remarkably well for permanent braces or for plating broken backs, arms and legs.

Behind the rugged grandeur of the Steel City and its products, is the less apparent but equally dramatic story of Pittsburgh's preëminence as a center of science and industrial research. This research is constantly creating new and better articles for the markets of the world and the comforts of mankind.

Mellon Institute, through its pure and applied researches, ministers to the humanities and to the industries. Extensive laboratories are maintained in the district by the U. S. Bureau of Mines and by the following world-known commercial enterprises: Aluminum Company of America, Carnegie-Illinois Steel Corporation, Gulf Oil Corporation, H. J. Heinz Company, Jones & Laughlin Steel Corporation, Pittsburgh Plate Glass Company, and Westinghouse Electric & Manufacturing Company.

From the laboratories of the Standard Chemical Company of Pittsburgh came the first radium produced in the United States. This gift to the medical profession of America was developed in 1913.

Air Hygiene Foundation, a national science organization supported by 250 industrial concerns throughout the country, maintains headquarters in Pittsburgh at Mellon Institute. The Foundation is working for the improvement of employee health in the nation's plants and mines, and for the prevention of occupational disease.

The city boasts five institutions of higher learning, all of which are well equipped for science studies. These institutions are University of Pittsburgh, Carnegie Institute of Technology, Duquesne University, Pennsylvania College for Women, and Mt. Mercy College.

The new home of Mellon Institute

A reversing mill at the Irvin Works of the Carnegie-Illinois Steel Corporation

Yes, Pittsburgh furnishes the eye-appealing answer to the dreams of countless Americans who wish to paint, see, hear, feel and record the march of human progress.

Pittsburgh is a workshop for the world, the gateway to the great American West, the home of new sights and

new experiences, spread over many hills and valleys, served by 1,547 bridges, through country rich in history, spectacular for its industry, and charming over its miles of ever-changing landscape and scenic beauty on the historic "Point" of three rivers—the birthplace of the "Beautiful Ohio."

Proper recreation and play is provided for everyone on 12,000 acres of playgrounds, 40 swimming pools, 75 tennis courts, and half dozen lakes, a zoo, and 38 golf courses—more golf courses than can be found in any other county in the United States.

And in the evening, after sundown, visitors may view the moon in its orbit and the Parade of Stars across the heavens, through the giant eyes of telescopes and cameras of the Allegheny Observatory and in the auditorium of the Buhl Planetarium.

Pittsburgh is for the first time to act as host to the American Public Health Association. You are assured of a warm welcome and a most enjoyable meeting. Reserve October 17-20 on your calendars!

ASSOCIATION NEWS

"This exhibit on
Public Health Administration
is sponsored by the
American Public Health Association."

MEMBERS of the Association visiting the New York World's Fair this year will read this caption on a plaque identifying the exhibit which they have made possible by their contributions.

Acknowledgment is made to the following individuals and organizations for their gifts to the exhibit fund:

Arlington Ailes, M.D.
Alabama Department of Public Health
I. Hope Alexander, M.D.
American Public Health Assn. Staff
G. F. Amyot, M.D.
Donald B. Armstrong, M.D.
Reginald M. Atwater, M.D.
William E. Ayling, M.D.
Charles A. Bailey, M.D.
Margaret W. Barnard, M.D.
Edward Bartow, Ph.D.
L. W. Bass, Ph.D.
Leona Baumgartner, M.D.

HEALTH CONSERVATION CONTESTS

WINNERS OF TENTH ANNUAL CITY HEALTH CONTEST

GROUP I (cities of over 500,000 population), first award, Cleveland, Ohio. Awards of merit in this group go to Buffalo, N. Y.; and Pittsburgh, Pa.

GROUP II (cities of 250,000 to 500,000 population), first award, Providence, R. I. Awards of merit in this group go to Memphis, Tenn.; Louisville, Ky.; Dallas, Tex.; and Cincinnati, Ohio.

GROUP III (cities of 100,000 to 250,000 population), first award, Grand Rapids, Mich. Awards of merit go to Reading, Pa.; Yonkers, N. Y.; and Erie, Pa.

GROUP IV (cities of 50,000 to 100,000 population), first award, Newton, Mass. Awards of merit to Madison, Wis.; and Greensboro, N. C. and Evanston, Ill., tied.

Group V (cities of 20,000 to 50,000 population), first award, Plainfield, N. J. Awards of merit go to Winona, Minn.; Orange, N. J.; and Stamford, Conn.

GROUP VI (cities of less than 20,000 population), first award, Englewood, N. J. Awards of merit go to Hibbing, Minn.; and Virginia, Minn.

In addition, special awards were given to Baltimore, Md.; Brookline, Mass.; Detroit, Mich.; Greenwich, Conn.; Hackensack, N. J.; Hartford, Conn.; Newark, N. J.; New Haven, Conn.; Pasadena, Calif.; Schenectady, N. Y.; and Syracuse, N. Y. Each of these cities has on two or more occasions won first award in its population group and has maintained its previous high standards during 1938.

WINNERS OF THE FIFTH ANNUAL RURAL HEALTH CONTEST

In the Northeastern Division the winner is Cattaraugus County, N. Y. Awards of merit go to Mecosta-Osceola District, Mich.; District 7, Mich. and Saginaw County, Mich., tied; Alger-Schoolcraft District, Mich.; Cortland County, N. Y.; Chippewa County, Mich.; Barnstable County, Mass.; and Berkshire District, Mass.

In the Eastern Division the Winner is Wicomico County, Md. Awards of merit go to Fayette County, Ky.; Mason County, Ky.; Montgomery County, Md.; Jefferson County, Ky.; Scott County, Ky.; Arlington County, Va.; Anderson County, Ky.; Barren County, Ky.; Hamilton County, Tenn.; and Orange-Person-Chatham Health Unit, N. C.

In the Southeastern Division the winner is Charleston County, S. C. Awards of merit go to Lauderdale County, Miss.; Brooks County, Ga.; Berkeley County, S. C.; Macon County, Ala.; and Pickens County, Ala.

In the North Central Division an award of merit goes to Gallatin County, Mont.

In the South Central Division awards of merit go to Dallas County, Tex.; Tyler-Smith County, Tex., and St. Mary's Parish, La.

In the Western Division the winner is Los Angeles County, Calif. Awards of merit go to Wasco County, Ore.; Clallam County, Wash.; Marion County, Ore.; Jackson

County, Ore.; and Spokane County, Wash. and Whitman County, Wash., tied.

Special awards for having won the Rural Health Contest twice in their respective geographical districts and for having maintained their previous high standards of achievement during 1938 go to Davidson County, Tenn.; El Paso County, Tex.; Pike County, Miss., and Shawnee County, Kans.

In the *Canadian Rural Health Contest* the winner is St. Jean-Iberville-Laprairie-Napier-

ville County Health Unit, Quebec. Awards of merit go to Terreboone County Health Unit, Quebec; Rimouski County Health Unit, Quebec; Argenteuil County Health Unit, Quebec; St. James-St. Vital County Health Unit, Manitoba; St. Hyacinthe-Rouville County Health Unit, Quebec; Temiscouata-Riviere du Loup County Health Unit, Quebec; Laviolette County Health Unit, Quebec; Nicolet County Health Unit, Quebec; and Matane County Health Unit, Quebec.

WINNERS OF 1938 SPECIAL CONTESTS

In the 1938 Special Contest for Tuberculosis Control, Hartford, Conn., and Newton, Mass., tied for first place. In addition an

award of merit goes to New Haven, Conn.

In the 1938 Special Contest for Syphilis Control the winner is Louisville, Ky.

SPONSOR OF THE CONTESTS

The City Health Contest is financed by a group of life insurance companies.* The Rural Health Contest is financed by the W. K. Kellogg Foundation of Battle Creek, Mich.

The Contest in Canada is sponsored jointly by the Canadian Public Health Association and the American Public Health Association.

* Life insurance companies financing this health project include:

Bankers Life Insurance Company
Bankers National Life Insurance Company
Berkshire Life Insurance Company
Business Mens Assurance Company
California-Western States Life Insurance Company
Capitol Life Insurance Company
Central Life Assurance Society
Franklin Life Insurance Company
General American Life Insurance Company
Great Southern Life Insurance Company
Guardian Life Insurance Company of America
Liberty National Life Insurance Company
Life and Casualty Insurance Company
Lincoln National Life Insurance Company
Massachusetts Mutual Life Insurance Company
Metropolitan Life Insurance Company
Midwest Life Insurance Company

Two special contests, one on Tuberculosis and one on Syphilis, are carried on in conjunction with the City Health Contest. Awards are made to those competing cities which appear to have the most comprehensive and effective programs for combating tuberculosis and syphilis.

Minnesota Mutual Life Insurance Company
Mutual Trust Life Insurance Company
National Life and Accident Insurance Company
New York Life Insurance Company
Northwestern National Life Insurance Company
Occidental Life Insurance Company
Old Line Life Insurance Company of America
Pacific Mutual Life Insurance Company
Provident Mutual Life Insurance Company
Republic National Life Insurance Company
Reserve Loan Life Insurance Company
Rockford Life Insurance Company
Southwestern Life Insurance Company
Sun Life Insurance Company
Travelers Insurance Company
United Benefit Life Insurance Company
Volunteer State Life Insurance Company
West Coast Life Insurance Company
Western Life Insurance Company

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

- A. J. Butler, M.D., C.P.H., Underwood Ave., Clinton, Tenn., Director, Anderson-Campbell County Health District
 Marshall C. Keith, M.D., State Health Department, Cheyenne, Wyo., State Health Officer
 James A. McCallum, M.D., C.P.H., Centreville, Md., Deputy State Health Officer
 William G. Rinchart, M.D., 211 Commerce Bldg., Pittsburg, Kans., City Health Officer
 Robert C. Strode, M.D., 220 Clifton Ave., Mount Holly, N. J., District Health Officer
 Stamatis G. Velonis, M.D., Nespelem, Wash., Deputy State Health Officer, Colville Indian Reservation
 James F. Worley, M.D., Box 1751, Juneau, Alaska, Senior Surgeon, U. S. Public Health Service, and Medical Director for Alaska, U. S. Indian Service

Laboratory Section

- Jacob M. Coblentz, M.S., 208 Science, Iowa State College, Ames, Iowa, Research Graduate Assistant
 Barton F. Hauenstein, M.D., 2100 City Hall, Buffalo, N. Y., Director of Laboratories, Dept. of Health
 Arthur P. Long, M.D., Dr.P.H., 198 Fair Oaks Park, Needham, Mass., Assistant Director, Division of Biologic Laboratories, Massachusetts Dept. of Public Health
 Theodore Marcus, M.Sc., 6 Columbia Road, Dorchester, Mass., Director, Massachusetts Dairy Laboratories
 Nicholas M. Molnar, M.S., 211 East 19th St., New York, N. Y., Director, Molnar Laboratories, and Director, Stuyvesant Polyclinic Laboratories
 Paul V. Woolley, Jr., M.D., 375 South St., Jamaica Plain, Boston, Mass., Assistant Director, Division of Biologic Laboratories, Massachusetts Dept. of Public Health

Vital Statistics Section

- Alpha K. Kenny, Box 485, Blountville, Tenn.

Public Health Engineering Section

- Ralph M. Davidson, M.S., Weid County Court House, Greeley, Colo., Sanitarian, Weid County Health Unit
 Walter F. Garcia, Wailuku, Maui, Hawaii, Sanitary Inspector, Territorial Board of Health
 Harry K. Gidley, B.S. in C.E., State Health

- Dept., Charleston, W. Va., Associate Sanitary Engineer
 Irving Reichman, B.C.E., 1855 Bogart Ave., New York, N. Y., Water Inspector, City of New York Dept. of Water Supply
 Yale Rosenfeld, B.S., C.P.H., 2207-26th Ave., San Francisco, Calif., Student, University of California
 James G. Terrill, Jr., C.E., Graduate House, Massachusetts Institute of Technology, Cambridge, Mass., Student
 Barringer F. Wingard, B.S., City Hall, Clinton, S. C., Health Officer

Industrial Hygiene Section

- Robert M. Kirk, B.S., 1616 State St., Harrisburg, Pa., Chemist, Division of Industrial Hygiene, Pennsylvania Dept. of Health

Food and Nutrition Section

- Milton L. Laing, M.S., Chemical Laboratory, Armour & Company, Chicago, Ill., Assistant Chief Chemist
 Helen Stacey, M.A., 82 MacDougal St., New York, N. Y., Nutrition Consultant, Henry Street Visiting Nurse Service

Child Hygiene Section

- Robert B. Hightower, M.D., Room 203, District Bldg., Washington, D. C., Assistant Director, School Medical Inspection, Health Dept.

Public Health Education Section

- Clennie E. Bailey, Sc.D., 1235 East 14th Ave., Apt. 32, Denver, Colo., Teacher of Hygiene and Public Health, University of Denver
 George H. Bischoff, M.D., 709 Pueblo, Boise, Idaho, Director, Maternal and Child Health, State Crippled Children's Division
 Mrs. Emily G. Bogert, 581 Gibson St., Akron, Colo., Vice-Commander, Woman's Field Army for Control of Cancer
 Rachel S. Browne, 326 Appleton St., Holyoke, Mass., Executive Secretary, Holyoke Tuberculosis Assoc.
 Mrs. H. Reed Edmunds, Box 467, Leesburg, Fla., Executive Secretary, Lake County Tuberculosis and Health Assoc.
 Milton A. Feinberg, B.S., 411 East 69th St., New York, N. Y., Field Secretary, Committee on Neighborhood Health Development, Dept. of Health
 Arthur H. German, B.Sc., 308 Key Bldg., Oklahoma City, Okla., Executive Secretary,

Tuberculosis Society of Oklahoma City
 A. Harry Ostrow, D.D.S., 203 District Bldg.,
 Washington, D. C., Director of Dental
 Services, District of Columbia Health Dept.
 Edward W. E. Schear, Ph.D., 107 West Park

 Elected Member 1935

EMPLOYMENT SERVICE

The Employment Service will register persons qualified in the public health field without charge.

Replies to these advertisements, when keyed, should be addressed to the American Public Health Association, 50 West 50th Street, New York, N. Y., identifying clearly the key number on the envelope.

POSITIONS WANTED

HEALTH OFFICERS

Unusually well qualified and experienced administrator; M.D., Johns Hopkins; M.P.H., Harvard; with broad experience in administering programs of medical care; is available. **A404**

Physician; M.D., Class A medical school; M.S.P.H., University of Michigan, 1937; now serving as district state health officer; seeks full-time city or city-county administrative position. **A367**

Well qualified physician; with C.P.H. from Johns Hopkins; experienced as school physician and in college teaching; will consider city or county administrative position or teaching and student health. **A383**

Physician; M.D., Vanderbilt University; Dr.P.H., Johns Hopkins; experienced as epidemiologist, health officer and professor of preventive medicine; seeks position as administrator or epidemiologist. **A397**

Physician, aged 30; M.D., University of Illinois; C.P.H., University of California; experienced as instructor in medicine and director of state Division of Epidemiology; desires position in communicable disease control or administration. **A399**

Physician; M.D., C.P.H.; 2 years' experience as district health officer; prefers to do venereal disease control work or epidemiology. **A345**

Well qualified physician, completing course in public health at University of Michigan, with special interests in tuberculosis and venereal disease control, seeks responsible appointment. Excellent references. **A406**

Physician; M.D., University of Minnesota, 1927; M.S., Columbia University, 1937; special training in tuberculosis and venereal disease, and administrative experience in CCC camp; wishes position as health officer. **A407**

Physician; M.D., Yale; M.S.P.H., Columbia; also short course for Health Officers, Vanderbilt; good clinical background; one year public health experience; will consider appointment in child health, epidemiology or public health administration. **A350**

Physician; M.D. degree from Class A medical school. Two years' internship in large city hospital; 14 years' general practice be-

fore entering public health activities; 12 years' full-time public health experience. Employed now with state department of health. Will consider opening with well organized city or state department in communicable disease division or epidemiology or both. Mid-west preferred. **A409**

Physician, M.D., class A medical school, M.S.P.H., University of Michigan, 1939. Ten years' experience in administrative full-time health programs. Seeks position in public health administrative position. **A373**

HEALTH EDUCATION

Health educator with excellent background of teaching experience in schools; M.S.P.H. from the University of Michigan in June; wishes a position where skill with educational sound film projection and other recognized technics will be appreciated. **H405**

Experienced director of health education, R.N. and college graduate, with excellent references, will consider health education or promotional position in the East. **A408**

LABORATORY

Physician; M.D., Northwestern; Dr.P.H., Johns Hopkins; broad experience in laboratory, teaching and epidemiological fields; will consider temporary position for summer, beginning in May, preferably in parasitology. **M293**

Physician; C.P.H., Harvard-Technology; experienced as bacteriologist and pathologist and director of state laboratories; desires position. **L208**

Experienced bacteriologist, Ph.D., 1934, with teaching in research background, particularly in relation to sanitation, seeks position as director of laboratory or teacher. **L370**

Experienced woman bacteriologist, Ph.D., University of Illinois 1937, wishes position in teaching or research. Excellent bibliography and references. **L410**

Bacteriologist, M.S. degree, experienced in university teaching, testing antiseptics, bacterial food poisoning, and industrial products, desires a laboratory or allied position. **L411**

Chemist and bacteriologist experienced in water supply, sewage, and public health

laboratory work. Five years' experience. B.S. 1933. Desires work in sanitation or general public health. L412

Chemist and Bacteriologist, B.Sc.; A.B.; B.S. in Ed.; M.S.P.H. from University of Michigan. Experience in field work as chemist. Serology training under Dr. Kahn at Ann Arbor, Mich. Three years' experience in public health laboratory work. Will consider position in public health field. L415

MATERNAL AND CHILD HEALTH

Woman physician, with excellent medical training and background of public health nursing experience, seeks position in maternity and infancy work. C376

Woman physician, graduate of University of Iowa, who has directed state bureau of maternal and child health, now employed, will consider another position. C318

ENGINEERING

Public Health Engineer, B.S. in Sanitary Engineering, University of California, 1937. Now completing training for C.P.H. in Public Health Engineering, University of California. Well trained in all phases of sanitation and other public health activities, including epidemiology, public health administration, health education, etc. Desires position as sanitary or public health engineer in municipal, county or state health department. E413

MISCELLANEOUS

Experienced librarian in the medical field, with knowledge of the literature, languages, editing, abstracting and reference work, desires position in research or editorial department of a public health organization. Available in the fall. M414

Situations Wanted

PUBLIC HEALTH PHYSICIAN—B.S., M.D., degrees eastern schools; CPH, Johns Hopkins School of Hygiene; five years, chief epidemiologist State Department of Health; for further information please write M. Burneice Larson, Director, Medical Bureau, Pittsfield Building, Chicago.

PUBLIC HEALTH NURSE—Graduate of a small school; graduate courses in pediatrics and communicable diseases; nine months' postgraduate training in public health nursing, Western Reserve; several years' successful hospital experience (supervising and executive); five years, public health nursing; for further information please write M. Burneice Larson, Director, Medical Bureau, Pittsfield Building, Chicago.

BACTERIOLOGIST—A.B., M.S., degrees, state university; ten years, city bacteriologist and chemist, city health department; for further information please write M. Burneice Larson, Director, Medical Bureau, Pittsfield Building, Chicago.

SOCIAL WORKER—B.A. and M.A. degrees; two years' graduate training, eastern school of social service work; two years, case worker in family department of Catholic charitable organization; field work was served in medical social service; has ability to carry responsibilities; for further information please write M. Burneice Larson, Director, Medical Bureau, Pittsfield Building, Chicago.

Situations Open

WANTED—Director of Health; physician; graduate recognized school of public health, with year's practical experience in public health field; beginning salary \$4,000; wealthy residential community, New England. No. PH-55, Medical Bureau, Pittsfield Building, Chicago.

WANTED—Public health nurse to assist supervisor of nurses, municipal public health department; midwest. No. PH-50, Medical Bureau, Pittsfield Building, Chicago.

WANTED—Registered nurse with college degree who has emphasized public health work; small southeastern college; \$125, maintenance. No.

PH-51, Medical Bureau, Pittsfield Building, Chicago.

WANTED—Graduate nurse-technician; college infirmary; 8-hour day, 5½ day week; month's paid vacation; \$1200-\$1400; midwest. No. PH-52, Medical Bureau, Pittsfield Building, Chicago.

WANTED—Qualified public health physician for immediate appointment as district health officer, midwestern state. No. PH-53, Medical Bureau, Pittsfield Building, Chicago.

WANTED—High school nurse, with degree, public health training; 5-day week, regular teaching hours; Chicago vicinity. No. PH-54, Medical Bureau, Pittsfield Building, Chicago.

NEWS FROM THE FIELD

THE NATIONAL HEALTH ACT OF 1939

A SUMMARY OF THE WAGNER BILL BEFORE THE U. S. CONGRESS

SENATOR Robert F. Wagner of New York has introduced the National Health Act of 1939 (S. 1620). The following is a summary of the main provisions of the Bill:

The National Health Act is intended to implement with concrete legislation the recommendations developed out of a 5 year inquiry recently reported by the Inter-departmental Committee to Coördinate Health and Welfare and other federal agencies.

The Bill utilizes the procedure of grants-in-aid from the federal government, familiar in various titles of the Social Security Act, which provides latitude to the states in the development of their own plans. In this Bill grants are made available for the purpose of establishing, expanding, and approving state programs for child and maternal health, for general public health and investigation, for the construction of needed hospitals and health centers, for general programs of medical care, and for insurance against loss of wages during periods of temporary disability. Federal administration is broken up between the Children's Bureau, the Public Health Service, and the Social Security Board.

Contrary to a general impression, there is no provision in the Act authorizing the federal government to furnish medical care. Administration in all cases is to be through the states, with a view to supplementing the existing efforts of the professions, the localities, charitable organizations, and hospitals. The Bill does not establish

a system of health insurance or require the states to do so. However, the states will be free to develop plans of their own choosing, subject to the establishment of necessary basic standards. Plans for medical care may be limited to those on relief or they may include others more fortunately situated and may be paid for by insurance contributions, by general revenue, or both. The method and scope of medical services are for the states to determine and they may include services rendered through existing private agencies or institutions.

Provision is made for participation by the federal government only where there is financial participation by the state. The state must provide either a state-wide program at the outset or plans for extension so that the program will be in effect in all political subdivisions of the state in need of the services not later than June 30, 1945. Except for the grants for disability compensation, the administration of the plan is to be by the state health agency, or at least there is to be supervision by the state health agency of any part of the plan administered by another state agency or by a political subdivision of the state.

The federal administrative officers may require the states to establish personnel standards on a merit basis and methods of establishing and maintaining standards of medical and institutional care and of remuneration for such care to be prescribed by the state agency after consultation with profes-

sional advisory committees. At each stage of state and federal administration provision is made for consultation with professional advisory councils composed of members of the professions and agencies, public and private, that furnish the particular services.

Federal grants are made available for the professional training of administrative and technical personnel. It is also required that the states provide for necessary working agreements between state administrative agencies concerned with various aspects of social insurance, public assistance, workmen's compensation, vocational rehabilitation, industrial hygiene and education.

The new appropriations authorized in the first year for all phases of the program, including the administrative costs, aggregate approximately \$80,000,000, exclusive of amounts which may be appropriated by Congress for aiding the states in the construction of needed tuberculosis and mental hospitals. This sum under the Bill will be gradually increased over a 10 year period and will be available to match sums appropriated by the states toward the cost of their respective programs. No new federal payroll taxes are authorized.

In order to make the available funds serve the interest of those localities which are in greatest need of the services, the Bill authorizes grants on a variable matching basis, depending on the relative financial resources of the several states, as determined by the per capita income of their inhabitants. The

federal grants will vary from $33\frac{1}{3}$ per cent to $66\frac{2}{3}$ per cent of the total sums expended by the states for various programs of public health and hospital construction. For programs of medical care, the matching ratio varies from $16\frac{2}{3}$ per cent to 50 per cent of total state expenditures. The intent of this provision is to raise the general level of health protection throughout the country, while reducing the existing wide variations among the states, and especially as between rural and urban areas.

In addition to various preventive and curative health services, the Bill authorizes grants-in-aid to states in establishing insurance plans providing cash benefits during periods of temporary disability. These insurance systems would protect the wage earner against an annual wage loss through disabling illness estimated to be more than \$1,000,000,000 per year. Federal grants for this purpose are authorized at a fixed matching ratio of $33\frac{1}{3}$ per cent of the total expenditures by the states.

Under this Bill the Children's Bureau is charged with the administration of grants for maternal and child welfare and for services to crippled and other physically handicapped children. The Public Health Service is charged with the administration of grants for general public health work and investigations and for hospitals and health centers. The grants for medical care and for disability compensation are to be administered by the Social Security Board.

SUMMER SCHOOL COURSES IN PUBLIC HEALTH

While the following list does not show all universities and technical schools offering summer courses in public health, it represents those who have replied to a questionnaire sent out by the American Public Health Association.

American National Red Cross

Courses in Teacher Training for Home Hygiene Instruction:

University of California, Los Angeles,
Calif.—June 26–August 4
Colorado State College, Fort Collins,
Colo.—July 8–August 18
Peabody College, Nashville, Tenn.—June
12–August 25

University of California, Berkeley, Calif.

June 26–August 4

General Bacteriology
Child Development
Physiology of the Growth and Development
of Children
Administration of the School Health Pro-
gram
Child Psychology
Nursing and Social Problems in the Con-
trol of Syphilis and Gonorrhea—3 weeks'
institute, June 26–July 14—under aus-
pices of University of California and the
State Department of Public Health
Introduction to Educational Psychology
General Psychology
Elementary Epidemiology *
Elementary Public Health *
Applied Hematology and Other Diagnostic
Procedures *

* These four courses are offered in the Inter-
session, May 15–June 23

University of California at Los Angeles, Los Angeles, Calif.

June 26–August 4

Elementary Bacteriology
Growth and Development of the Child
Adolescence
Child Guidance
Mental Hygiene
The Nursery School
Administration of the School Health Pro-
gram

Administration, Supervision, and Teaching
of Sight-Saving Classes
Recreational Leadership
Physiology of Exercise

International Malaria Course for 1939 (under direction of Professor Giuseppe Bastianelli)

[For information on these two courses, write to the Medical & Health Dept., I.R.C.E., Via Lazzaro Spallanzani 1A, Rome.]

NATIONAL CONFERENCE FOR COÖPERATION IN SCHOOL HEALTH EDUCATION

RECOGNITION of the opportunities for developing more comprehensive and better coördinated programs of school health education throughout the United States culminated in a 2 day conference of some 70 delegates of 40 national organizations at Rockefeller Center, New York, N. Y., in November, 1938. Preliminary plans for the conference were developed by representatives of the National Education Association, the U. S. Public Health Service, the American Social Hygiene Association, and the National Health Council. Reports from delegates gave a colorful picture of the variety of ways that different organizations operate, of the wealth of diversified services, of the many groups served, and of the difficulties which hinder full attainment of objectives.

Members of the conference stressed the importance of health education in the entire community and the desirability of interrelating school health education and public health education. There are many national health and educational agencies already well organized for service in the health field. From this preliminary conference there resulted a plan for the organization of a National Conference for Coöperation in School Health Education. "To meet more effectively the recognized needs of the schools . . . for making the resources of all agencies more readily available through coördination of efforts."

An executive committee is in the process of organization, and operating codes have been tentatively drawn for the guidance of the executive committee and of the National Conference to be composed of representatives selected by the national agencies represented at

the first Conference and others to be added. These plans will be submitted in the near future for the consideration of the participating agencies. The chairman of the Conference during these stages of organization is Professor Ira V. Hiscock of Yale University, President of the National Health Council; and the secretary is Dr. N. P. Neilson, Executive Secretary of the American Association for Health, Physical Education and Recreation, a department of the National Education Association.

WPA TO BUILD HEALTH DEPARTMENT LABORATORIES IN ILLINOIS

ACCORDING to a recent announcement, 20 laboratories will be constructed by the WPA for the Illinois State Department of Health.

Subject to federal approval, the laboratories will be situated where facilities are inadequate and will not compete with or duplicate existing public or private laboratories. They are not to be used for treatment.

PACIFIC SCIENCE CONGRESS

THE National Research Council has announced that the Sixth Pacific Science Congress will be held under its auspices in San Francisco and vicinity between the dates July 24 and August 12.

Certain of the sessions will be held on the grounds of the Golden Gate International Exposition, certain on the campus of Stanford University near Palo Alto and certain sessions on the University of California campus at Berkeley. The meetings of the Western Branch of the American Public Health Association will be held during part of this period, July 23-28, in Oakland.

Dean Charles B. Lipman of the University of California, Berkeley, is the Chairman of the Committee of the Pacific Science Congress.

ROBERT WILLIAM PHILIP

THE February issue of *Tubercle* carries a notice of the death of Robert William Philip.

"The death of Sir Robert Philip marks an epoch in the history of the anti-tuberculosis campaign. He must surely be regarded as a leader in a public health crusade."

Lady Philip died suddenly in Edinburgh within a month of her husband's death.

RED CROSS MEDICAL ADVISORY COM- MITTEE ON HEALTH ACTIVITIES

CREATION of a Medical Advisory Committee to the American Red Cross is announced by Chairman Norman H. Davis.

Dr. Livingston Farrand of New York, who was chairman of the Central Committee of the American Red Cross from 1919 to 1921, has accepted chairmanship of the new committee. Other members are:

Dr. Thomas Parran, Surgeon General of the United States Public Health Service

Dr. Waller S. Leathers, Dean of the Medical School of Vanderbilt University, Nashville, Tenn.

Dr. David P. Barr, Professor of Medicine, Washington University School of Medicine, St. Louis, Mo.

Dr. Martha M. Eliot, Assistant Chief of the Children's Bureau, Washington, D. C.

Rear Admiral Ross T. McIntire, Surgeon General of the U. S. Navy

Major General Charles R. Reynolds, Surgeon General of the U. S. Army

Dr. Edwards A. Park, Pediatrician-in-Chief of Johns Hopkins Hospital, Baltimore, Md.

PENNSYLVANIA REQUIRES CANCER AND DIABETES CASES REGISTERED

A NEW regulation requiring the registration of cancer and diabetes cases has been announced by the Pennsylvania State Health Department.

These two diseases must be reported in the same manner as communicable diseases, and results of treatment, if any, must be included in the report.

VOCATIONAL GUIDANCE FOR PUBLIC HEALTH NURSES

THE Nursing Bureau of Manhattan and Bronx, Inc., New York, N. Y., opens a vocational-placement service to public health nurses and the field on May 1, 1939. The service has the tentative approval of the Committee on Vocational Counseling of N.O.P.H.N. Full approval is dependent upon analysis of the service in action.

Letha Allen, R.N., formerly Director of the Public Health Nursing Organization of Eastchester, Tuckahoe, N. Y., has been appointed Secretary of Public Health Placements. The Nursing Bureau of Manhattan and Bronx, Inc., has been conducting a placement-vocational service for private practice and institutional nurses since 1933. The service to public health nurses and nursing organizations is now added because a need for it in New York City was created when the public health nursing service rendered by Joint Vocational Service in New York City was transferred last July to the Nurse Placement Service in Chicago.

All grades of positions will be handled, the service covering the entire United States.

TEACHING HEALTH CENTER AT COLUMBIA UNIVERSITY

THE opening of the new laboratories and classrooms of the De Lamar Institute of Public Health at the Presbyterian Columbia Medical Center, 168th St. and Broadway, New York, N. Y., has been announced by Dean Willard C. Rappleye, Dean of the Columbia University College of Physicians and Surgeons. The building has been erected through an agreement between the Presbyterian Hospital, Columbia University, and the New York City Department of Health and will serve the Washington Heights and Riverside Districts of the Borough of Manhattan.

This building is one of five similar health centers in New York City through which the health department will provide facilities whereby medical students can participate actively in all phases of public health work, including epidemiology, nursing service, supervision of school children and coöperation with social welfare agencies.

The first four floors of the center will be used by the city as headquarters for maternal care, child welfare, nursing and other public health services. Upper floors will include equipment for the institute and will contain a model classroom with provisions for controlling temperature, volume, humidity, the character of dust and the bacterial content of the air.

BIOLOGICAL ABSTRACTS

ANSWERING the demand from many scientists, *Biological Abstracts*, beginning with the January, 1939, issue, has been separated into individual sections, so that persons may now subscribe to whichever sections interest them. In addition, the complete form will continue to be published. Section C—*Abstracts of Microbiology, Immunology and Parasitology*, which will be of most interest to public health workers, includes immunology, bacteriology, viruses, parasitology, protozoology and helminthology. The index to the complete volume is included with each section.

INCUBATOR SERVICE

INCUBATOR service for premature infants has been inaugurated at the Red Hook-Gowanus Health Center of the New York City Health Department. As part of the program to lower the infant death rate, four portable incubators have been purchased, and letters have been sent to physicians residing in this district informing them of the service.

PERSONALS

Central States

FILIP C. FORSBECK, M.D.,* formerly Associate Director of the Michigan Bureau of Communicable Disease, Lansing, has entered the Reserve Corps of the U. S. Public Health Service with the rank of surgeon. He will be stationed in Cincinnati where he will be engaged in work on the epidemiology of gastroenteritis, complementing the work of the Stream Pollution Investigations Station. Dr. Forsbeck is Secretary of the Epidemiology Section of the A.P.H.A.

C. D. HART, M.D., C.P.H.,* Director of District Department of Health No. 6, Newberry, Mich., has been appointed Health Officer of the City of Savannah, and Chatham County, Ga.

DR. JOHN A. MCINTYRE has been appointed Health Officer of Owatonna, Minn., succeeding the late Dr. JEROME F. SMERSH.

DR. DENNIS M. O'DONNELL has been appointed Health Officer of Ortonville, Minn.

Eastern States

LIEUTENANT-COLONEL A. P. HITCHENS, M.C., U.S.A.,* now assigned to the University of Pennsylvania Medical School, Philadelphia, has been appointed by permission of Secretary Woodring, of the War Department, as George S. Pepper Professor of Public Health and Preventive Medicine at the University of Pennsylvania. For the present Dr. Hitchens will be in charge of the undergraduate and graduate teaching in Public Health and Preventive Medicine, in addition to the courses in Military Medicine.

DR. JOHN J. SHAW, of Philadelphia, Pa., has been appointed State Sec-

retary of Health of Pennsylvania, to succeed Dr. EDITH McBRIDE-DEXTER.

DR. GEORGE S. STEVENSON has been appointed Medical Director of the National Committee for Mental Hygiene, New York, N. Y. He succeeds Dr. CLARENCE M. HINCKS, who has asked to be relieved of his duties except as part-time Field Consultant, in order to give more time to the work of the National Committee for Mental Hygiene of Canada, of which he is the General Director and Founder.

DR. ALEXANDER HAMILTON STEWART, of Indiana, Pa., has been appointed Deputy Secretary of Health of Pennsylvania.

Southern States

LIVINGSTON L. BLAIR, of Washington, D. C., has been appointed Assistant National Director of the Junior Red Cross.

DR. JOHN W. DABBS, of Geneva, Ala., has been appointed Health Officer of Geneva County, succeeding Dr. WALTER J. BROAD, who has resigned to accept a position in the Division of Venereal Diseases, Alabama State Department of Health.

DR. ROBERT H. HIGHTOWER, who has been instructor in pediatrics under the auspices of the department of clinical and medical education of the Medical Society of Virginia, has resigned to accept a position as Assistant Director of School Medical Inspection in the District of Columbia.

JOSEPH A. MORRIS, M.D.,† of Franklinton, N. C., recently retired as Health Officer of Granville County, after about 20 years of service.

DR. BALLARD L. NORWOOD, JR., now serving at a CCC camp at Greenwood, S. C., has been appointed Health Officer of Granville County, N. C., to succeed JOSEPH A. MORRIS,

* Fellow A.P.H.A.

† Member A.P.H.A.

M.D.,† resigned. Dr. Norwood will take a course in public health at the University of North Carolina before assuming the position July 1.

DR. HENRY E. SIGERIST, Director of the Institute of Medicine, Johns Hopkins University School of Medicine, Baltimore, Md., will lecture during August, September, and October in universities of the Union of South Africa, under a visiting lectureship.

Western States

DR. EDWIN L. BRUCK has been appointed a member of the advisory council to the San Francisco Department of Health, San Francisco, Calif., succeeding DR. WILLIAM C. VOORSANGER.

JOHN M. COLLINS, M.D.,† Seattle, Wash., Acting Health Officer, King County, Wash., resigned March 24, 1939, to accept appointment as First Lieutenant, Medical Corps, Regular Army.

DR. WENDELL H. HUTCHENS, of Portland, Ore., was recently appointed a new member of the Oregon State Board of Health.

DR. CORNELIUS MARTIN MILLS, of Oakland, Calif., has been appointed Chief of the Crippled Children's Services of the California State Department of Public Health. He will have charge of the Department's activities under the California Crippled Child Act and those for the relief of the physically handicapped made possible through the provision of social security funds.

FREDERICK D. STRICKER, M.D.,* of Portland, Ore., was elected Executive Secretary and State Health Officer of the State Board of Health at a recent meeting.

DR. HARVEY A. WOODS, of Ashland, Ore., was appointed a new member of

the Oregon State Board of Health.

Canada

JOHN J. HEAGERTY, M.D., D.P.H.,† Chief Executive Assistant of the Department of Pensions and National Health, Ottawa, Ont., has been appointed Director of Public Health Services of Canada.

Foreign

DR. ROBERTO BACHI, medical statistician and economist, formerly professor of Economics at the University of Rome but now exiled from Italy, has been appointed to the staff of the new Medical Center on Mt. Scopus, Jerusalem, Palestine.

DR. EMILIO ENRICO FRANCO, former Professor of Pathological Surgery and Anatomy at the Royal University of Pisa, exiled from Italy, has been appointed to the staff of the new Medical Center on Mt. Scopus, Jerusalem, Palestine.

DR. LUDWIG HALBERSTAEDTER, exiled from Italy, has become associated with the Hadassah Medical Organization in Palestine, Jerusalem.

PROFESSOR BERNHARD ZONDEK, co-discoverer of the Ascheim-Zondek test, is exiled from Italy, and has become associated with the Hadassah Medical Organization in Palestine, Jerusalem.

DEATHS

DR. JAMES MORSELL GASSAWAY, Senior Surgeon, retired, of Cairo, Ill., died March 5, at the age of 91. He was the oldest member of the U. S. Public Health Service, and was associated with the Service for 63 years.

JACOB G. LIPMAN, PH.D.,* of the Experiment Station, New Brunswick, N. J., died April 19.

CHARLOTTE A. STICKNEY, M.D.,† Pediatrician, Division of Child Hygiene, Minnesota Department of Health, St. Paul, Minn., died February 26.

* Fellow A.P.H.A.

† Member A.P.H.A.

Results Obtained in an Extensive Tuberculosis Case Finding Program in a Large City*

BRUCE H. DOUGLAS, M.D., F.A.P.H.A., AND
GAIUS E. HARMON, M.D., F.A.P.H.A.

*Controller of Tuberculosis; and Director of Statistical Studies;
Department of Health, Detroit, Mich.*

THE elimination of tuberculosis is dependent upon the detection, isolation, and proper treatment of every case of tuberculosis before it has reached an advanced stage. To assist in the early detection of cases, the Department of Health of Detroit inaugurated a plan of Tuberculosis Case Finding in December, 1936, involving the medical participation principle.

The essential features of this plan, described in detail elsewhere,¹⁻⁴ were the following:

1. The necessary examinations were to be made by the private physician in his office.
2. The city was to pay for the examination of those who could not afford to pay.
3. Reports of all examinations made under the plan were to be submitted to the Department of Health.

For administrative purposes the city was divided into two parts: one known

as the Special District comprised those sections of the city in which the incidence of tuberculosis was known to be excessively high, as compared with the city as a whole. In this district it was desired that everyone should be examined. With this end in view nurses made a house-to-house canvass to give information about tuberculosis, and to urge everyone to go to his family physician for examination. Physicians were urged to examine their entire clientele living in this district for tuberculosis. The rest of the city comprised the other part. In this district physicians were only supposed to examine known contacts to cases, and individuals whom they might suspect of having tuberculosis. It is thus evident that it was intended that there should be a difference between the two districts as to the number and class of persons to be examined; in one, everyone, and in the other, only contacts or suspects were to be examined.

This study deals with the results ob-

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 27, 1938.

tained during the first 18 months of the operation of the Medical Participation Plan adopted for finding cases of tuberculosis. The figures submitted are based upon preliminary tabulations of reports as they were received from week to week, a condition which did not permit extensive cross-checking for errors and duplications. This method of summarizing the data did not make it possible to be sure that the different groups which one might desire to compare would always include the same persons. Furthermore, it follows from this limitation that the same people may not have been included in the numerators and denominators of the various ratios that would naturally be employed. It is hoped that a complete statistical analysis will be made later by means of punch-cards and mechanical tabulation.

It should be understood that the figures in the tables that follow refer to tuberculin tests and X-ray examinations respectively, and not to individuals. For some individuals duplication of work is included in the figures. In the main, the von Pirquet method of tuberculin testing was used by the private physician, although the Mantoux test was also used to some extent.

GENERAL RESULTS

The general results are presented in Table I. It will be noted that during the 18 month period 114,831 tuberculin tests were reported, and of these, 31,803, or 27.8 per cent, were positive. The results of 27,084 X-ray examinations were reported. These were done by 26 specialists in roentgenology and 38 general practitioners who did their own X-ray work. The doing of these tuberculin tests and X-ray examinations resulted in the discovery of 633 verified cases of active tuberculosis. Approximately 2 per cent of the persons having positive tuberculin tests were found to have active tuberculosis. It may well be emphasized that the 2 per cent only included those cases of tuberculosis of such a degree of activity as to call for treatment.

The percentage of tuberculin tests reported to be positive increased from 24.2 per cent for the first period to 30.5 per cent for the last period. In the absence of any marked change in the age distribution of those tested from period to period this increase probably was due to an improvement in the accuracy with which the tuberculin tests were done by the participating physicians. This might well be expected in view of the

TABLE I
Tuberculosis Case Finding, Detroit
Distribution of Tuberculin Tests and X-ray Examinations According to the Period
During Which They Were Done and Result

December 3, 1936, to July 1, 1938

Six Month Period	Tuberculin Tests Reported				X-ray Examinations Reported		Verified Cases Found
	Total	Positive	Negative	Per cent Positive	Per cent of Positive Tuberculin Tests		
					Total		
First	41,434	10,010	31,424	24.2	7,403	74.0	213
Second	33,295	9,565	23,730	28.7	8,757	91.2	204
Third	40,102	12,228	27,874	30.5	10,924	89.3	216
Total	114,831	31,803	83,028	27.8	27,084	85.2	633
Cases per 1,000 Tuberculin Tests					5.51		
Cases per 1,000 Positive Tuberculin Tests					19.90		
Cases per 1,000 X-ray Examinations					23.37		

TABLE II

*Tuberculosis Case Finding, Detroit**Distribution of Tuberculin Tests as Classified by the Reporting Physicians*

April 16, 1937, to July 1, 1938

Class	Tuberculin Tests Reported			Per cent Positive
	Total	Positive	Negative	
Contact	7,299	2,986	4,313	40.9
Suspect	26,858	8,716	18,142	32.5
Unclassified	65,257	17,306	47,951	26.5
Total	99,414	29,008	70,406	29.2

fact that the tests were done by 705 different physicians. With the passage of time the percentage of people having a positive tuberculin test and not going for an X-ray examination, has diminished. For the entire period under consideration approximately 15 per cent of those having a positive tuberculin test did not have an X-ray examination. If we relate the verified cases to the number of X-ray examinations, which approximates the number of persons who had both a positive tuberculin test and an X-ray made, then 2.3 per cent of the positive tuberculin reactors were found to have active tuberculosis.

The doctors were asked to classify those on whom they did tuberculin tests as to whether or not they were con-

tacts, suspects, or in neither of these classes. Table II indicates that the percentage of positive tuberculin reactors, as would be expected, was highest among the contacts. Next follows the suspects, and finally the unclassified group had the lowest percentage of positive reactors. This relationship was found to be true whether one were dealing with the persons living in the Special District, or living outside the Special District.

AGE

Beginning April 16, 1937, the tuberculin tests were classified according to the age of the persons to whom they related. The results are presented in Table III, and it is evident—as would be expected—that the percentage of

TABLE III

*Tuberculosis Case Finding, Detroit**Distribution of Tuberculin Tests and Cases According to Age of Individuals Tested*

April 16, 1937, to July 1, 1938

Age	Tuberculin Tests Reported			Cases	Cases per 1,000 Tuberculin Tests	Cases per 1,000 Positive Tuberculin Tests
	Total	Positive	Per cent Positive			
0-9 Years	20,585	1,216	5.9	25	1.21	20.56
10-19 "	22,441	4,174	18.9	90	4.01	21.56
20-29 "	21,304	8,102	38.0	162	7.60	20.00
30 Years and Over	34,862	15,449	44.3	262	7.52	16.96
Age Not Stated	222	67	30.2	2	9.01	29.85
Total	99,414	29,008	29.2	541	5.44	18.65

TABLE IV

*Tuberculosis Case Finding, Detroit**Relationship Between Age and Diagnosis for All New Cases*

December 3, 1936, to July 1, 1938

Age	Diagnosis					Total	Adult Types Per cent Minimal
	Childhood Active	Minimal	Moderately Advanced	Far Advanced	Pleurisy with Effusion and Other Forms		
0- 9 Years	29	4	1	0	0	34	80.0
10-19 "	13	29	31	18	8	99	37.2
20-29 "	4	58	77	48	13	200	31.7
30 Years and Over	3	69	121	86	18	297	25.0
Age Not Stated	..	3	3	100.0
Total	49	163	230	152	39	633	29.9

positive tuberculin tests increased with the age of the persons tested. It is also evident that approximately 2 per cent of the positive tuberculin tests, regardless of age, were found to be associated with active tuberculosis in those to whom they related.

For the first 6 months of 1938 a larger number of age groups was employed in making the tabulations. The results corresponded in a general way with those of Table III. At age 50 and over, about 50 per cent of the persons tested were positive.

Table IV presents the relationship between age and the verified diagnosis for all new cases discovered under the Medical Participation program during the 18 months of its operation. It

should be noted particularly that, if only adult types of active tuberculosis be considered, then 29.9 per cent were discovered in the minimal stage; also, that the percentage of minimal cases found decreased with increasing age. Cases were not considered to be in a minimal stage unless they were definitely active and needed treatment. If all minimal cases had been included irrespective of activity, then 53.4 per cent rather than 29.9 per cent were discovered in the minimal stage. It is well understood that the percentage of minimal cases found in different communities depends upon varying interpretations of what a minimal case is, so that the results obtained in different places may not be comparable.

TABLE V

*Tuberculosis Case Finding, Detroit**Relation of Tuberculin Tests to Cases Found According to Area of Residence*

April 16, 1937, to December 29, 1937

Area of Residence	Tuberculin Tests			Cases	Cases per 1,000 Total Tests	Cases per 1,000 Positive Tests
	Total	Positive	Per cent Positive			
Special District	48,472	13,148	27.1	238	4.91	18.10
Outside Special District	10,840	3,632	33.5	87	8.03	23.95
Total	59,312	16,780	28.3	325	5.48	19.37

RESIDENCE

In accordance with the administrative procedure outlined at the beginning of the paper, it was possible to classify the tuberculin tests and cases according to two areas of residence, namely, the Special District and the rest of the city. The result of this classification is presented in Table V. It will be noted that, of the tuberculin tests done on those residing in the Special District, 27.1 per cent were positive as compared with 33.5 per cent for those living outside the Special District. In view of the fact that everyone was to be tested in the Special District, and that only contacts and suspects were to be tested among those living outside the Special District, the result would seem to be what might have been expected.

It is also evident that, regardless of the area of residence, approximately 2 per cent of the positive tuberculin tests related to people who were found to have active tuberculosis. It is known that a number of those who had a positive tuberculin test did not have an X-ray examination, and therefore this percentage is somewhat too low. If the ratio between cases and tuberculin tests be based on total tuberculin tests rather than on positive tests, then those living inside the Special District had a smaller number of cases per 1,000 tested than was true of persons living outside the Special District. This, however, would be expected because, of those persons

living outside the Special District a larger percentage was positive, and therefore the number of cases found per total number examined would naturally be larger.

For Table VI the distribution of tuberculin tests according to the residence of the persons concerned has been based upon census areas. In a rough way Census Areas A, B, C, K, and L correspond to the Special District in Table V. If Table VI be compared with Table V, it will be noted that the percentage of tuberculin tests that were positive for people living in the Special District, as compared with those living in the rest of the city is approximately the same; also that the cases per 1,000 total tests and cases per 1,000 positive tests, are higher for persons living in the Special District than for those living in the rest of the city. This is the reverse of what was found for the period covered by Table V. These differences call for comment, and the following explanations may be advanced for the evident contradiction.

1. There is a possibility that the efficiency of the tuberculin testing done on persons living in the Special District may have improved more with the passage of time than was the case with the testing done on those not living in the Special District.

2. The restriction placed upon physicians, that only contacts and suspects were to be tuberculin tested, may not have been rigidly adhered to. That this may have been the case is supported by the fact that for the first period covered by Table V, approxi-

*Tuberculosis Case Finding, Detroit**Relation of Tuberculin Tests to Cases Found According to Area of Residence*

January 1, 1938, to July 1, 1938

<i>Census Areas of Residence</i>	<i>Tuberculin Tests</i>			<i>Cases</i>	<i>Cases per 1,000 Total Tests</i>	<i>Cases per 1,000 Positive Tests</i>
	<i>Total</i>	<i>Positive</i>	<i>Per cent Positive</i>			
A, B, C, K, & L	27,910	8,392	30.1	167	5.98	19.90
All Other Areas	12,192	3,836	31.5	49	4.02	12.77
Total	40,102	12,228	30.5	216	5.39	17.66

mately 82 per cent of the tuberculin tests related to persons residing in the Special District; while for the period covered by Table VI, only 70 per cent of the people having tuberculin tests resided in the Special District.

It does not seem to be epidemiologically sound to compare the results obtained in testing people residing in the Special District with the results obtained for those residing in the rest of the city. The differences obtained are probably due to differences in the way the people were selected for examination, rather than to any difference in the incidence of tuberculous infection as judged by the tuberculin test. The differences observed may be due to such factors as the following:

- 1. That in the Special District everyone was supposed to be examined, while in the rest of the city only contacts and suspects were expected to be examined.
- 2. It is conceivable that the doctors in one district may have had greater efficiency in carrying out and reading the tuberculin tests done.

3. There is a possibility that there was a difference in the age distribution of the people residing in the two districts respectively.

For the first 6 months of 1938 a distribution was made of the tuberculin tests done on children falling in the age group, 0-4 years, inclusive, according to the census area of residence of the children concerned. This, of course, removes the age variable when different sections of the city are compared, but does not eliminate factors 1 and 2 listed above. The results of this distribution are presented in Table VII. It should be noted that the percentage of positive tuberculin tests for children living in Census Areas A, B, C, K, and L, respectively, varied comparatively little. In other words, there seems to be very little evidence that for children there was any difference in the percentage of those exhibiting a positive tuberculin reaction when subdivisions of the Special District were compared. A special

Total	3,389	139	3,250	4.1

study of certain subdivisions of the Special District also showed that this result held when persons of all ages were considered. This is what would naturally be expected as Census Areas A, B, C, K, and L are located in the section of Detroit where the environmental and economic conditions are the poorest.

If the percentages of positive tuberculin tests of children, presented in Table VII, for the other census areas be compared, it should be remembered that the differences may depend upon the method of sampling, or size of sample, rather than upon any actual difference between the various census areas in the incidence of infection as judged by the tuberculin test.

If the Special District be compared with the rest of the city, it is found that 4.7 per cent of the children living in the former area, as compared with 2.8 per cent in the latter, were tuberculin positive. This is perhaps tentative evidence that a greater percentage of children living in the poorer section of Detroit are infected with *Mycobacterium tuberculosis* than is the case among those living in the better sections of the city.

SUMMARY

The result of the first 18 months' activities in finding cases of tuberculosis under the Medical Participation Plan may be summarized as follows:

1. 114,831 tuberculin tests were reported by 705 individual physicians. Of these tests, 27.8 per cent were considered to be positive.
2. 27,084 X-ray examinations were reported by 64 physicians.
3. These tests and examinations resulted in

the finding of 633 verified cases of active tuberculosis.

4. Approximately 2 per cent of the positive tuberculin tests related to persons found to have active tuberculosis, and this percentage in a general way was independent of age and residence.

5. Of tuberculin tests stated by the doctors to relate to contacts, 40.9 per cent were positive. Of those relating to suspects, 32.5 per cent were positive, and of those not related to either of these classes, 26.5 per cent were positive.

6. The percentage of positive tests was definitely associated with the age of the persons to whom they related. The percentage of positive tests increased with age, reaching a maximum of 50 per cent at about age 50.

7. Of the cases of adult type of active tuberculosis discovered, 29.9 per cent were in a minimal stage as defined.

8. If adult type of active tuberculosis be considered, the percentage of minimal cases found declined with increasing age.

9. Because of the sampling restrictions imposed, a comparison of the results obtained for persons living in the poor section of the city—that is, the one where a high incidence of tuberculosis existed—with the results obtained for persons living in the rest of the city, was unsatisfactory. The two sections are really not comparable. Some evidence was obtained which indicates that within the poor district there was no marked difference from one subdivision to another in the incidence of tuberculosis as judged by the tuberculin test.

Production of Mottled Enamel Halted by a Change in Common Water Supply*

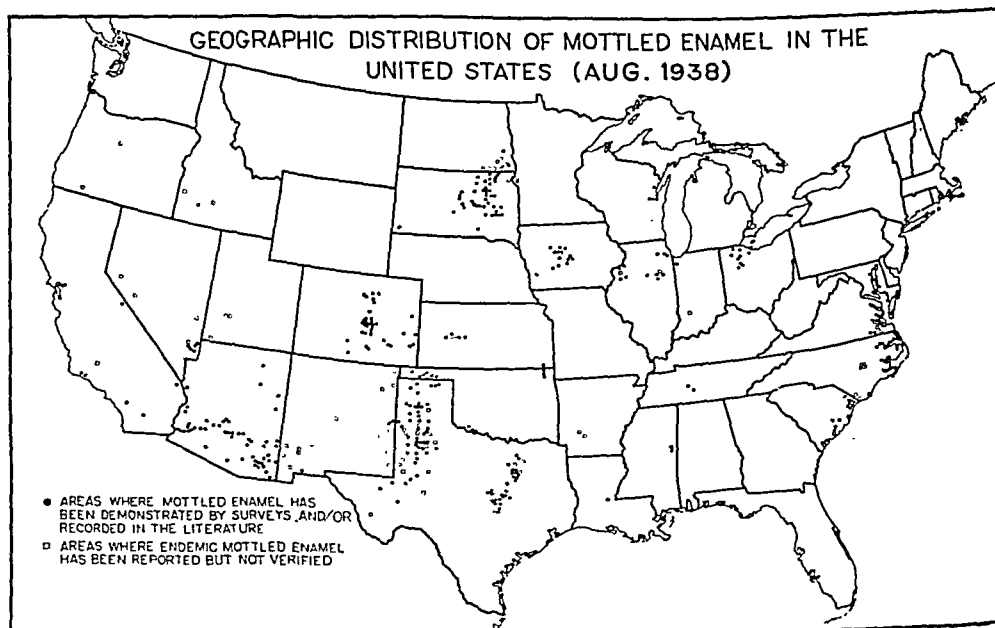

H. TRENDLEY DEAN, D.D.S., F.A.P.H.A., AND
FREDERICK S. McKAY, D.D.S.

*Dental Surgeon, Division of Infectious Diseases, National Institute of Health, U. S. Public Health Service, Washington, D. C., and
Consultant, U. S. Public Health Service, New York, N. Y.*

IN the United States at present there are about 375 known areas, divided among 26 states where mottled enamel of varying degrees of severity is found. This large number of areas made avail-

able for study various communities whose common water supplies contained fluorides in different concentrations. This, in turn, permitted detailed quantitative study of concomitant variations.

water supply and the clinical effect. Quantitative increase in the fluoride concentration of the domestic water was concurrent with an increase in the amount and degree of clinical severity. The direct verification of concomitant variation is shown in Table I. In order to present these tabular data graphically, a numerical index of clinical severity was computed by giving a definite weight to each of the several degrees of clinical affection. The following weights were given to each diagnosis: Normal, 0; Questionable, 0.5; Very Mild, 1; Mild, 2; Moderate, 3; and Severe, 4. The weighted index of clinical severity was then plotted against the fluoride concentration of the communal water supply. Figure II shows a rather precise quantitative correlation.

munities where the endemicity of mottled enamel had been confirmed by survey, changed their communal water supply from one containing a fluoride concentration now known to be sufficient to produce endemic mottled enamel to one practically free of fluorides: Each community presented the indispensable conditions of a susceptible population* using the "new" water supply and a sufficient lapse in time (8-10 years) for a study of the consequent

differences. The two sets of circumstances were similar in all respects save for the one difference, the change in the water supply. The surveys made prior to the change in the water supply and the resurvey made after the requisite lapse of time were made by either one or the other of the writers. The communities studied were: Oakley, Ida., Bauxite, Ark., and Andover, S. D.

Oakley, Ida.—The first instance of a community changing its public water supply solely for the purpose of preventing mottled enamel is that of Oakley, Ida. A survey of this community was made by one of us² in February, 1925. Seventy-eight children whose histories indicated continuous residence and uninterrupted use of the common water supply were examined. The incidence of affection was 100 per cent. The common water supply of Oakley at the time of the survey was obtained from a warm spring. Following the survey, the community on July 1, 1925, changed its water supply, the new supply being obtained from a nearby cold water spring. The selection of this water was based on the observation that the 4 children of a family using this spring were free of mottled enamel.

Approximately 7½ years (February, 1933) after the change in the common water supply, Oakley was resurveyed.³ Twenty-four children born since the change in the water supply were examined. *All showed normal calcification* in those permanent teeth which at that time had erupted. According to analyses³ made by Churchill, the "old" Oakley water contained 6.0 p. p. m. of fluorine; the "new" supply, less than 0.5 p. p. m.

Bauxite, Ark.—In February, 1928, a mottled enamel survey of Bauxite was made by Kempf and McKay.⁴ Sixty of the 62 children of continuous residence examined showed mottled enamel, generally of a severe type. Of the two classified as normal,

Kempf and McKay recorded in a footnote that although the homes of these children were piped for the city water, it appears that it was only used occasionally for domestic purposes. The water used by the 60 affected children examined during the 1928 survey was obtained from deep wells and, according to Churchill,⁵ contained 13.7 p. p. m. of fluoride (F).

In May, 1928, the Bauxite water supply was changed, the "new" supply being obtained from the nearby Saline River. A resurvey⁶ by the writers in March, 1938, showed that of the 45 children born since the change in the water supply, only 2 showed even the mildest form of mottled enamel.* The "new" filtered river water supply is practically free of fluorides, containing less than that determinable routinely (0.2 p.p.m.).

Andover, S. D.—In 1916, one of us (F. S. McK.) made a qualitative survey of the school children of Andover and found mottled enamel endemic, associated with the use of the water from the city artesian well supply.⁷ In 1928 this deep well water supply† failed and the community was forced to change from the 800' artesian to a dug shallow well 22' deep. An examination of the school children by one of the writers (H.T.D.) in April, 1938, showed that

* A possible explanation of the two "very mild" cases is contained in the detailed report of the Bauxite resurvey (*Pub. Health Rep.*, 53:1736-1748 (Sept. 30), 1938). The fluoride (F) content of the "old" Bauxite water was so unusually high, 13.7 p.p.m., that the question of antepartum maternal fluorosis and subsequent transfer of small amounts of fluorides in the mother's milk cannot be excluded. The 7 year old child with the "very mild" diagnosis was nursed 15 months. Consideration might also be given to possible fluoride deposits from the "old" supply in the water pipes and cooking utensils.

† The fluoride content of the "old" Andover (S.D.) deep well water is not known, but presumptive evidence based on clinical mottled enamel among those who calcified their permanent teeth while using this water indicates that it contained fluorides, probably in the neighborhood of 2.5-3.0 p.p.m. of fluorine. Wells of comparable depth in the immediate rural district are likewise producing mottled enamel.

TABLE II

SUMMARY OF THE FINDINGS IN SURVEYS OF THREE COMMUNITIES WHERE THE PRODUCTION OF MOTTLED ENAMEL WAS HALTED BY A CHANGE IN THE COMMON WATER SUPPLY

FINDINGS OF ORIGINAL SURVEY																	INCIDENCE OF MOTTLED ENAMEL AMONG USERS OF "OLD" WATER SUPPLY	FLUORIDE (F) CONTENT OF "OLD" WATER SUPPLY	INCIDENCE OF MOTTLED ENAMEL AMONG USERS OF "NEW" WATER SUPPLY	FLUORIDE (F) CONTENT OF "NEW" WATER SUPPLY

† ON THE BASIS OF CLINICAL EVIDENCE, ARTESIAN WELL SUPPLY PRESUMABLY CONTAINED ABOUT 2.5 TO 3.0 PARTS PER MILLION OF FLUORIDE (F).

the 14 children, 6-10 years of age, born since the change in the water supply, presented normal calcification of the permanent teeth. The "new" water supply used by these children was found to be free of toxic amounts of fluoride.

DISCUSSION

An analysis of the findings, by age groupings, of the resurveys recorded in Table II shows the striking differences resulting from the mere change in the water supply. Those in the higher age groups who calcified their permanent teeth while using the "old" water supply show an incidence of mottled enamel comparable to that observed during the original survey. Next a definite decrease in the percentage incidence of affection becomes manifest in those children whose dental calcifi-

cation period overlapped the change in the water supply (age group who calcified their teeth while using both water supplies), and finally the relative freedom from mottled enamel in those born subsequent to the change in the water supply. These decreasing percentage incidences of clinical affection speak for themselves. With respect to Oakley, they were 92, 20, and 0; Bauxite, 100, 52, and 4; and Andover, 69, 37, and 0, respectively.

While we are fully aware that the number of observations is comparatively small, the effects noted are consistent. The observations, moreover, were limited to those children constantly exposed to the risk of the disease, namely, they were born in the community, had in general always resided there, and had always used the common water supply for both drinking and

cooking. In the case of the resurvey at Bauxite, the facts with respect to residence and water consumption were verified in each instance by an interview with the child's parent.

In specific water-borne diseases, the time intervening between the elimination of the antecedent cause and the nonappearance of the pathological entity is relatively short. The opposite characteristic of endemic dental fluorosis (mottled enamel) makes it unique among the water-borne diseases. An interval in time between 8 to 10 years is required to carry out a human experiment that furnishes clinical proof that the development of the disease has stopped.

With the report on the results obtained at Oakley, Ida., Bauxite, Ark., and Andover, S. D., showing that the production of mottled enamel has actually been stopped by the mere change in the water supply from one containing concentration of fluorides toxic to calcifying dental enamel to one practically free of fluoride (or less than 1.0 p.p.m.), the most conclusive and direct proof that fluoride in the drinking water is the primary cause of human mottled enamel has been presented. The separate steps in the complete chain of evidence may now be summarized as follows:

1. The evidence pointing to mottled enamel being a water borne disease.^{8, 7}

2. The finding of fluorides in domestic waters associated with the production of mottled enamel.^{9, 5, 10}

3. The experimental production of dental lesions in white rats and dogs by waters from endemic areas and waters to which fluoride has been added.^{9, 11, 12}

4. Quantitative epidemiological studies on human mottled enamel correlating the fluoride concentration of the domestic water with the degrees of clinical severity.^{13, 1}

5. And finally, after the lapse of the necessary interval of 8 to 10 years, the clinical evidence that the production of human mottled enamel had been halted by merely changing the common water supply from one containing fluorides in concentrations toxic

to calcifying dental enamel to one practically free of fluorides.^{3, 6}

SUMMARY

1. The production of the endemic hypoplasia of the permanent teeth known as mottled enamel has been halted at Oakley, Ida.; Bauxite, Ark.; and Andover, S. D., by simply changing the common water supply from one containing amounts of fluorides toxic to calcifying dental enamel to one whose fluoride content does not exceed the permissible maximum, 1 p.p.m.

2. Oakley, Ida., and Bauxite, Ark., are the first known instances of communities abandoning an otherwise satisfactory common water supply solely for the definite purpose of preventing mottled enamel; and in itself likewise represents the first instance where a common water supply was changed solely for the purpose of preventing a dental disease.

3. The unusually long interval in time (8-10 years) before the clinical effects resultant from a change in the water supply may be observed clinically, is unique in epidemiological investigations of water-borne diseases.

4. With the report on the results obtained in three endemic areas, showing that the production of mottled enamel has actually been stopped by the mere change in the water supply from one containing concentrations of fluoride toxic to calcifying dental enamel to one practically free of fluoride, the most conclusive and direct proof that fluoride in the domestic water is the primary cause of human mottled enamel, has been presented.

Public Health Administration

IT is indeed the practitioners of medicine, and chiefly the general practitioners, who by their observations at the bedside have pointed out the way to preserve health and have proclaimed the need for public health administration in season and out of season with a most laudable persistence.

Nay, more, the comprehensive character of public health legislation and administration, as we see it today, came into being through public remonstrances by the medical profession against the disorderly state of the early sanitary laws.—Health and The State, Walter Elliot, *Brit.M.J.* Feb. 25, 1939.

In-Service Training for Doctors and Nurses*

LEONA BAUMGARTNER, M.D., PH.D.

Department of Health, New York, N. Y.

ALTHOUGH the phrase "in-service training" is one of more recent origin, the principles underlying such efforts have been practised ever since human beings first learned to work together. One must first know exactly what the job is and why it is to be done. Next he must be taught which of the several methods of accomplishing the end is the best. He must then be put under a type of leadership which will allow him to do his job this way and which will foster desirable working relationships and attitudes.

These principles probably sound too simple but in the complexity of planning our programs we often neglect them. We assume that we know our objectives—mouthing the words we have written in our manuals. We use methods to accomplish our ends which we have not critically examined nor experimentally tested for effectiveness. We do not recognize that the attitude toward the job and the working relationships of our staff are often the chief stumbling blocks in the path of efficient service. Perhaps these errors in not thinking through our problems have led to the perfunctory performance which characterizes so much of our school health work.

The principles we have outlined are applicable both to the training of the employee who is just entering service and to the one who needs revitalizing in his job.

What is the job? Assuredly, not to find out how many correctable defects there are per child—not to build up the service so that the total number of nursing home visits shall be increased from year to year—but to serve Johnny Jones, the patient. "To serve the child" is, however, much too vague an objective—for this question, "What is my job?" must be answered in as direct terms as possible. For example, we may say that a part of the school nurse's job is to coöperate with the teacher in the follow-up work. But what in our given school situation is the exact way to do this? What will be the nurse's share in this job? The teacher's? Do they know each other's responsibilities? The answers to these questions must be specific. Does the teacher or the nurse have the better opportunity to procure proper dental care for the children in this school?

Our second principle—knowing how the job can best be done—demands that we know the problems involved. Still considering the rapport between nurse and teacher, let us suppose that we have decided that a regular conference between the two is a method we have selected to promote "follow-up" work. But we must discover what

* Based on a paper presented at the Joint Session of the American School Health Association and the Child Hygiene Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 27, 1938.

problems both the teacher and the nurse face in securing dental aid for Johnny, what information the nurse can give about the clinic facilities available, or what she found out when she visited in the home last week. What does the teacher learn from Johnny as she meets him daily in the classroom? Then, together they may propose a method of handling the problem, test it out, and finally arrive at a solution which will be applicable for all the children in this grade.

Today's solution may, however, not be tomorrow's. We must, particularly for employees long in service, substitute an interest in today's problems for blind adherence to yesterday's solutions. We must test out our procedures repeatedly and be ever on the alert when we inquire into how or why things are done for an inflexible reply, "That is the way we do it." This answer too often implies that the critical attitude is no longer in operation.

The third principle is to afford the employee a type of leadership which will allow him to do his specific job in the best way. I happen to believe in that democratic type of leadership which allows for group participation and group determination of objectives and methods. Some administrators argue that this method is more time consuming. It may be for the immediate present, but in a profession like public health with its complicated problems and its ever changing frontiers, the employee must meet many problems individually, he must adapt what he has to what is needed, and he must be able to follow new procedures from time to time. It, therefore, seems wiser to equip him with a thorough understanding of the philosophy of what we are trying to do, and to allow him to participate in planning the program. He will then feel it is his own and carry it out more efficiently than if he were merely ordered to proceed.

METHODS OF STAFF TRAINING

The Department of Health in New York City has for the past two years carried on an in-service training program in accord with these principles. It has been unusually fortunate in having a group devoting its attention during this time solely to problems of staff education.

Report of these activities is made now only by request, for so short an experimental period makes it impossible to evaluate results. However it does seem possible to offer a critique of the teaching methods which have been used. Inspiration for these remarks is drawn from three sources: the Astoria school health study,¹ a project in staff education for nurses,² and a general training program in the department.

Each training venture has begun with an analysis not only of what the job is but what the training and experience of the staff are. Thus in the school situation, personnel cards were first made out showing where each physician and nurse had received professional education and what experience each had had—not only in medicine and nursing but in teaching, writing, etc. We were then in a better position to judge what subject materials should be emphasized and at what level we could begin.

Ways of inaugurating such training programs and the difficulties which are encountered could be discussed at some length but it seems more pertinent to confine the discussion to the teaching methods which have been used. The training of employees long in service will be stressed, for with the exception of one experiment with an unusually large group of new nurses entering the department, our experience is based on the training of the permanent staff of part-time physicians and full-time nurses in school and child health services.

THE LARGE MEETING AND THE LECTURE

A widely used method of staff training is the large staff meeting at which some one or two pertinent topics are discussed, often in lecture form by an outside expert. Despite its limitations, which are well recognized by all authorities in the field on adult education, this method has been found useful. Our group of 175 school physicians, for example, had little pride in the specific profession of being a *school* doctor. We used vacation times to bring them together for "school health institutes"—21 half-day sessions with speakers on cardiac disease, child psychology, administrative problems, childhood tuberculosis, etc. The programs were determined partially by the suggestions the physicians sent in.

The morale and interest of the group improved markedly following these sessions. We were careful to choose distinguished speakers—but speakers who we knew had something practical to offer our group. No matter how distinguished the speaker, at least 30 minutes were spent to discuss with him in advance of the meeting the problems we faced. Often we found it valuable to stress how this point of view—applicable at another time, perhaps—might not meet today's needs in our department. For example, a very practical pediatrician who was asked to speak on endocrinological problems in school children, said he had long wished for an opportunity to urge school physicians to send children into clinics for early diagnosis of endocrinopathies. We told him our problems in having insufficient staff to get even a child with 20/100 vision to the oculist for the glasses that would enable her to see the blackboard, and our problem with the mother who took fat Johnny to the clinic, only to be told after a long series of elaborate tests, that he should eat less and come back in 9 months for a check-up. Could we get her to go to a clinic again when

sister Mary was found to have a marked hearing loss? No, she had been there last year and nothing happened. Our specialist had never considered these problems.

After this preliminary conversation he came to us with an excellent presentation of the clinical aspects of endocrinological problems, emphasizing the ones which really should be taken to a consultant because therapy might be of benefit and the ones for which little could be done anyway so the child could as well be watched in school.

So the large meeting may be useful—to build morale, and sometimes to "put over" an idea the staff has been slow to accept until it came from someone they considered to be an authority. It should not be assumed, however, that the employee will often be stirred to action by a lecture or that his deeply ingrained habits will thereby be changed.

THE SMALL GROUP AND COMMITTEE

From the point of view of effective teaching the small conference group is usually more influential than the lecture. Here the group can attack problems directly, can organize itself, seek information from a variety of sources, and can work directly in the field. The problems are more practical ones—the solutions often more workable than those concocted in the administrator's office. The use of such employee groups is unlimited—and with wise leadership a source of constant inspiration to the officer responsible for the service as well as an excellent teaching device.

Such conferences are often of more value if all of those concerned in a given service are included. Many problems could not be solved until we had both the physician and nurse around the same conference table. Only then were we able to discover a real answer to the simple question of who should

do what in the school medical room. Another problem may demand that the teacher be at the conference. Ideas expressed at the small conference table can be tried out until we finally discover the best service which doctor, nurse, and teacher can give as a team.

Keeping careful records of these group meetings and circularizing the minutes increases the interest in them. We have even developed a mimeographed journal out of one such group. All of us need recognition and approval—and particularly in a job which tends to become a routine one. Assisting the school physician or nurse to find satisfaction in his or her work is a part of the training program—and the recognition which comes through the journal or report sent to the rest of the staff builds ego as well as being of some intrinsic value.

THE TRAINING CENTER

Another teaching device is the training center. By this we mean a typical unit of service which can be used for teaching the employee while he or she is actually "on the job." No more than the routine staff is assigned to care for the service in this center, and there is no additional equipment. One center now in use for instructing physicians and nurses of our well baby clinics has for example, a "floating" staff of doctor and nurse who are attached to the center to take the place of those who must leave their own work at a baby station to come to the center. The "student" physician and nurse are at present staying one month in the training center. They work here under supervision and guidance. There is plenty of time for discussion and analysis of problems and for frequent staff meetings. The doctor goes on ward rounds in an adjacent medical school pediatric department to refresh his knowledge of the diagnosis and treatment of sick children. Both nurse and

physician visit and participate in special dental and child guidance clinics. Special technics in vision and hearing tests for preschool children may be taught those who will use them. A nutritionist conducts conferences on home relief budgets, costs of infant formulae, etc.

Many teaching devices are used. The doctor may be asked to check all the charts at the end of the clinic and choose which babies should be visited by the nurse. The nurse and doctor together make some of these visits—sometimes on cases which the doctor has written up—sometimes on cases which some other physician has recommended for a home visit. Various problems of special interest are studied. Suppose our doctor is interested in what dosage of cod liver oil seems to be effective in preventing rickets. Why not see what the charts show? It is his research problem, and his disappointment when he cannot find the data he needs in these poorly kept records may be translated into better record keeping.*

The "floating staff" and this student staff meet from time to time to discuss problems—perhaps ones the "floating" staff has found in the field station. Even the supervisors of the student staff are brought in, for everyone must know and understand the program. One pediatrician and one nurse constitute the full-time teaching staff assigned to the center. The educational staff for special topics is borrowed from many sources in the community, for we want our staff not only to learn department routines but to see how we can cooperate with other agencies. After one month the student staff goes back into its own station where an additional teaching physician is assigned to assist

* Improving the quality of the records kept is an important problem in our service. We have, therefore, tried as many devices as possible to stimulate an interest in and an understanding of the need of better records. All these above listed procedures are useful. For another experience of this kind, see reference 3.

with following through the instruction begun in the center and to direct any new ventures.

The training center acts also as an experimental laboratory in which to test new procedures. The experimental attitude stimulates a more critical point of view and through it we are often able to teach some of the points we have long wished to emphasize concerning the service itself.

We have had some experience in which only the physician came to the center—a center in which he did not participate actively in the program and in which the problem approach was not widely used. This was not successful and therefore we have developed this other type of training center.

We have not established a training center for school physicians and nurses. We do not feel that as yet we have reached a point where we are ready for an elaborate training program for this personnel. The school health study unit is analyzing the respective rôles of physician, nurse, and teacher in the complicated school situation in a few schools, but we are not as yet ready to superimpose the procedures used there on the other 600 schools in the city. For, as stated previously, we believe that we must have a fairly clear idea of what the job is before we start a training program.

THE PROBLEM APPROACH

In both the small group and the training center, we have emphasized the problem approach for we believe it to be a most valuable teaching device. It may also be applied to larger groups. We have, for example, about 150 school physicians who are hired on a 12 month basis but work in schools only 10, leaving some time free during the summer. This year we decided that sending school physicians out to visit in homes might emphasize the economic, hereditary, and social factors involved in

nutrition. The group had had a few lectures on the subject. An outline was provided with the questions we hoped they would learn to ask in a case of this kind. Preliminary sessions outlined our objectives and attitudes and presented facts of current food costs, home relief allowances, etc. About 5,000 visits were made in the homes of children whom these doctors had previously diagnosed as "malnourished." They were asked to select from the group visited the children they thought would be benefitted by additional supervision in special health classes. We have not as yet been able to analyze the results of this program but our first reports indicate that the plan had value as a teaching device; and, moreover, it brought us suggestions for our program of health education. Almost twice as many families, in the doctor's opinion, were ignorant of foods and food values as were ignorant of the principles of family budgeting. Our first job, then, would appear to be to give these families a fundamental knowledge of nutrition before we teach them how to spend their available funds to buy these foods. So the problem approach acts not only as a teaching device for the staff but brings to light valuable "hunches" for future plans.

THE EXCHANGE SERVICE

Outside influences may be effectively brought into a staff training program. Does your doctor need additional pediatric training or would closer contact with the clinic to which he refers children benefit your service? Why not arrange for an exchange, in which the hospital resident has some field experience in your department's well baby clinics or schools and your doctor goes back to the hospital service again? Or, perhaps, your school physician would welcome some clinical sessions in your local hospital for contagious diseases? Or as he becomes more aware of the

child's personality, should he attend a child guidance clinic? We have used several of these schemes with some measure of success.

We have also tried on two occasions to send physicians to postgraduate medical schools for training courses but have found it difficult to select from a curriculum designed for the private practitioner courses which meet the needs of our physicians who are not concerned with therapeutics.

OTHER AIDS

There are many other tools which may be of assistance in the in-service training program. The envelope or package library with selected reprints, pamphlets, or small books on a given subject, is valuable, particularly, when the staff has helped select the materials. Building up a reference library for the staff to use is another teaching device and can lead as well to a wider use of the existing library facilities. Circularizing the announcements of open medical and nursing society meetings, adult education forums on pertinent topics, may be just the extra stimulus needed to get the mildly interested to attend.

CONCLUSION

In conclusion we wish to point out that pre-service training is one thing and that in-service training is another. The latter demands that the employee be taught what his job is, how it can best be done, and that he be afforded the type of leadership which allows him to do the job this way. Moreover, the in-service training program is often more concerned with changing attitudes than with teaching specific skills. It is, therefore, necessary to understand the philosophy underlying the service and to study the relationships of the specific job. This is not an easy task—and no one of the several technics which have been described does the trick. After all, the effective training program, as we understand it, is no sleight-of-hand performance, but an ever deepening understanding of what our jobs are, a process of growth which is never completed.

Safe Operation of Degreasing Tanks Using Trichlorethylene*

of Labor, New York, N. Y.*

THE oil and grease films which form on the surfaces of metal objects during their manufacture must be removed before the parts can be successfully plated, enameled, or painted. Several methods of degreasing have been developed including washing in a suitable oil and grease solvent. This method is widely used at the present time, particularly for the degreasing of small metal parts, and the solvent commonly employed is trichlorethylene, a chlorinated hydrocarbon.

The utilization of trichlorethylene in degreasing depends principally on its solvent action on oils and greases. It has the advantage of being non-inflammable and non-explosive.

Trichlorethylene is a heavy, low-boiling, colorless liquid with an ethereal odor. The most important physical and chemical properties are shown in opposite list.

Trichlorethylene vapor is stable on heating † to temperatures up to 257° F. (125° C.) but continued heating above this temperature in the presence of oxygen causes decomposition with cor-

rosive acid formation (HCl). To inhibit such decomposition it is customary for the commercial solvent to contain small quantities of anti-oxidants.¹ Such inhibitors also prevent photochemical decomposition due to light.

Although trichlorethylene is non-inflammable,† at high temperatures such as occur in gas flames, electric heaters, and burning tobacco, its vapors may

decompose with the formation of corrosive and toxic substances such as hydrochloric acid and phosgene. To prevent inhalation of these, the combustion products from open flames must, therefore, be vented so as to be disseminated safely outside of the building, and smoking in the vicinity of equipment using trichlorethylene must be prohibited.

Trichlorethylene may also be decomposed on prolonged heating in the presence of finely powdered aluminum. This is due to the catalytic effect of aluminum chloride that is first formed. Because of this whenever there is aluminum dust or small chips on the parts to be cleaned, frothing may occur with accompanying bad odors, both indicative of decomposition. The addition of water to the trichlorethylene in the first wash tank as an extreme measure will prevent such decomposition when cleaning aluminum parts.

PHYSIOLOGICAL ACTION

While various authors may disagree on the physiological damage resulting from breathing small concentrations of trichlorethylene it is rather generally agreed that it is toxic and that continued exposure to trichlorethylene vapors constitutes a potential health hazard.

The New York State Department of Labor² studied three individuals who were exposed to trichlorethylene vapors and found symptoms referable to the gastrointestinal and central nervous systems, such as nausea, dizziness, diminished vision, headache, and general ill feeling. Operators of trichlorethylene degreasing tanks frequently complain of headache, dizziness, and nausea.

In the operation of a trichlorethylene degreasing tank, the solvent is heated to the boiling point with the consequent generation of concentrated vapor in the tank over the boiling liquid. The parts

to be cleaned are dipped into the liquid and then suspended in the vapor zone for rinsing before withdrawing from the tank. A condenser built into the tank walls cools the vapor, causing it to condense and return to the liquid supply, thus utilizing the solvent over and over. A well adjusted balance between heat input, cooling capacity, rate of input of metal, and cleanliness of the solvent is required in order to insure the continuous operation of the cycle without escape of excessive quantities of the vapor from the tank. The constant generation of vapor, however, establishes a potential health hazard which becomes real when the operating balance between the liquid and the vapor is not constantly maintained. Because the loss of trichlorethylene vapor from the tank represents an increase in operating cost, the matter of proper operation assumes economic as well as hygienic importance and is thus more likely to be watched. However, degreasing equipment of this type is widely used in small manufacturing plants where quarters may be limited and supervision and maintenance poor, and the potential hazard associated with the use of trichlorethylene in such establishments is therefore greater than that existing in large plants. Hence, it is important to inquire into the requirements for proper design and safe location and operation of degreasing tanks and to determine the need for and design of ventilating systems for such equipment. This report deals with such an inquiry involving the survey of 50 plants in metropolitan New York with the detailed study of 15 of these. The plants were selected at random to give a good sample of conditions and include 26 of one manufacture, 20 of another, and 4 of home-made construction. In size the tanks varied from 140 sq. in. to 15 sq. ft. and were located in rooms varying from 2,000 to 375,000 cu. ft. in volume.

FIGURE I—Diagrammatic sketch of degreasing tank

**DESIGN OF TANK**

The degreasing equipment in its simplest form consists of a metal tank with heating elements in the bottom for heating the solvent, a water condenser around the upper walls of the tank for cooling and condensing the vapor, with a condensate trough below the condenser into which the condensed solvent drains and from which it flows back into the boiling liquid. The walls of the tank extend well above the condenser to provide adequate free-board above the concentrated vapor level to protect contents against external drafts and the drag out of solvent. For cleaning, a distilling arrangement is provided to permit removing the clean distillate

from the tank, and a suitable sump drain allows for the removal of the sludge and other residue from the bottom of the tank. A cover is provided for closing the tank when not in use. A simple tank is shown diagrammatically in Figure I. There are many variations from this simple design. In one type of tank three separate compartments are provided for washing, rinsing, and drying respectively. Another type allows for immersion in the vapor only. In all these modifications, however, there is no essential departure from the basic cycle of operation outlined above although the efficiency of operation may be improved.

The design of the heating element and the cooling system calls for a careful thermal balance with just enough heat supplied to keep the solvent boiling as the work passes through the tank and sufficient cooling in the condensing zone to maintain a definite maximum vapor level at all times including the period of maximum heat input. The thermal balance is best maintained by thermostatic control of the heating element and also of the dew level. The optimum water temperature at the inlet is about 70° and at the outlet approximately 90° F. The coolest point in the condensing zone should not fall below the dew point temperature of the room to prevent the condensing of water from the air which would increase the diffusibility of the solvent vapor. The maximum vapor level should be maintained at a height above the liquid level of approximately 0.6 times the width of the tank and with a free-board distance from the dew level to the lip of the tank of 15". Among the tanks investigated the free-board height varied from 2" to 20" with a median value of 14".

When gas is used as the heating medium, adequate venting of the combustion chamber to the outside atmosphere must be provided, not only to remove products of combustion, but also to remove hydrochloric acid, phosgene, and other products of heat decomposition of the trichlorethylene vapor. Because of the corrosive nature of these decomposition products it is essential that the vent pipes be constructed wholly of corrosion-resisting materials.

Safety thermostats of the manual re-set type should be installed above the operating vapor level and also immersed in the liquid when the latter is heated by gas or electricity. The function of the first is to shut off the heat when the concentrated trichlorethylene vapor for any reason rises above its normal operating level, while the second

operates to limit the temperature of the heated solvent to prevent too rapid boiling and possibly decomposition. For steam heated tanks a pressure reducing valve is required in the steam line to limit the pressure to 25 lbs. per sq. in.

Facilities for cleaning include a distilling arrangement by means of which the clean distillate is removed from the tank into a separate container, leaving the oil, grease, and other residue in the tank as a sludge, part of which may be removed through a sump drain. The viscous sludge, however, must be removed by scraping, and a suitable side cleanout door is required for this purpose.

Most of the foregoing design requirements have been incorporated in degreasing tanks of standard commercial manufacture and in addition the large tanks are commonly of the enclosed type with automatic feeding of the parts to be cleaned. This type of equipment is more independent of external drafts and also, because of its fixed rate of feed, less subject to fluctuating load than is the manually operated apparatus. The advantages of the enclosed tank and automatic feed are so great that small units are also being so built. Every encouragement should be given to this development.

SIZE OF TANK

Employ a tank large enough to permit the complete immersion of the parts to be cleaned in the liquid solvent and later in the vapor. In one plant over-size parts were being cleaned in a small tank with the part actually projecting above the top of the tank. The hot solvent was applied by means of a long-handle dipper well above the condenser with consequent escape of large quantities of vapor.

OPERATION

The manufacturers of degreasing tanks have prepared comprehensive in-

structions for the safe operation of their equipment. These instructions include information relative to speed of operation, precautions against decomposition of the solvent, technic of cleaning tank, etc., and they should be carefully studied and followed in the plant operation.

SPEED OF OPERATION

The rate at which parts are put through the degreasing tank affects the thermal balance between the boiling solvent and the vapor zone and thus influences the efficiency of cleaning. It also has a direct bearing upon the escape of solvent from the tank. At high speed the parts may come out with liquid solvent still adhering to them and also the rapid movement of the basket and objects into and out of the tank causes a disturbance which results in the escape of vapor-laden air. The importance of controlling the operating speed is clearly shown by the following case report:

Three old tanks were operated at a high production rate in a small room (2,000 cu. ft.) with a great deal of external air movement in the neighborhood of the tanks, with the consequent escape of vapors in considerable amounts. Cleaned parts were also found to have liquid solvent adhering to them after removal from the tank. The concentration of organic vapor at the operator's breathing level was found to be 500 p.p.m.* Following this study the old tanks were replaced by equipment of the latest design; the external drafts were eliminated; and a ventilated table was provided for the temporary holding of the cleaned parts until they were dry and cool. The production rate, however, continued at a high level and a second investigation showed that the average concentration of vapor had been reduced only to 300 p.p.m. in spite of the great improvement in equipment and working conditions.

A rate of feed of parts through the degreasing tank of 8-12' per minute is generally recommended and should be

carefully followed. It is important also to follow the manufacturer's instructions with respect to the holding period in the hot liquid and in the vapor zone. In the liquid bath the parts should be held long enough to be thoroughly washed but should not be allowed to reach the temperature of the boiling solvent. The parts must remain in the vapor zone, however, until they do reach the vapor temperature, at which point condensation ceases and the parts will then be dry as soon as they have been raised above the vapor level. Consideration must be given to the shape of the parts since those with cavities, fine cracks or seams, or parts that rest closely in the basket require a longer washing period, and also there is greater danger of carrying liquid solvent out of the tank.

CONTAMINATION AND DECOMPOSITION OF SOLVENT

The solvent becomes dirty with use. This contamination increases its boiling point and thus changes the thermal balance in the apparatus. If allowed to increase too far there is danger of heat decomposition which results in the liberation of free acid in the bath. Cleaning of parts freshly dipped in an acid bath will also increase the acidity of the solvent. In operation, therefore, the solvent must be maintained in a clean condition by frequent distilling and cleaning of the tank and through proper adjustment, its reaction should be maintained slightly alkaline. The importance of this control in connection with the cleaning of aluminum parts has already been shown.

In use the solvent also becomes contaminated with water which upsets the efficient operation of the equipment and increases the escape of solvent from the tank. The water must be removed at frequent intervals and this is best done by an automatic water separator built into the degreasing tank.

* All vapor concentrations reported in this paper were determined by means of a portable interferometer calibrated for trichlorethylene vapor. The limit of accuracy of this instrument is ± 20 p.p.m.

FIGURE II—Tank located by window and fan—high solvent loss

FIGURE III—Tank favorably located in large room

CLEANING

The amount of work done and the quantity of oil and dirt removed determine the frequency with which the solvent and machine should be cleaned. In general, the boiling point of the solvent should not be allowed to exceed 195° F. or the specific gravity to drop below 1.25, and these indices may be used to determine when cleaning is required.

The tank cleaning cycle is as follows: The solvent is boiled and the condensate removed into a separate container by suitable adjustment of the valves in the pipe line leading from the condensate trough. Boiling is continued until all solvent is removed, after which the sump valve is opened to permit the removal of oil and other liquid residue. Metal chips, mud, and other solid residue must be removed by scraping and for this a cleanout door is required on the side of the tank through which the sludge is removed by means of a long-handle scraper of suitable design. Otherwise the operator is forced to bend over the tank and thus expose himself to extremely high concentrations of vapor. It is clear that the solvent, liquid residue, and sludge should be confined as much as possible to minimize the escape of vapor. Cleaning is best done out of regular plant working hours, and the operator should be provided with a suitable respirator for use during the cleaning period. A cartridge type of respirator for absorption of organic vapors is best for this work, with a new cartridge used for each cleaning. The importance of careful control of the cleaning technic is attested to by the frequent complaints on the part of the operators, of dizziness and nausea during cleaning.

COOLING CLEANED PARTS

The cleaned objects come from the degreasing tank at a high temperature and in some plants it is customary to

cool them for immediate use. Exhaust ventilation to the outside rather than positive blowing should be used when an air stream is required for rapid cooling of cleaned objects. This method should also be used for drying parts, when there is danger of dragout of solvent. Thus, in one plant we found a vapor concentration of 420 p.p.m. during the cooling period where positive air was used as compared with a level well below 100 p.p.m. during the actual cleaning operation. In spite of the fact that the tank was located in a very large room (150,000 cu. ft.) the average exposure was high because of this bad practice.

LOSS OF SOLVENT

In a properly designed and operated tank, the solvent loss should be maintained at a low figure, and in practice the actual loss incurred constitutes a good measure of efficient operation and control of the health hazard. Our survey revealed that the solvent loss varied from 0.3 to 15 gal. per sq. ft. of tank area per 100 hrs. of operation with a median value of 3.5. The high losses were associated with careless operation and bad location with respect to drafts. The tank shown in Figure II is well located hygienically but badly from the standpoint of solvent loss.

LOCATION OF TANK

SIZE OF ROOM

For the most part the degreasing tanks were located in large rooms, only 10 being found in rooms less than 10,000 cu. ft. in volume. In the detailed study of the 15 plants the beneficial effect of natural dilution of the vapor was observed in all cases where the room volume was 20,000 cu. ft. or more and no disturbing drafts were present. Thus, in 4 different rooms varying from 20,000 to 150,000 cu. ft. in volume and provided with general ventilation at the rate of 5-12 air changes per hr., the concentration of

TABLE I

Vapor Concentration in Relation to Rate of Ventilation in Small Rooms

Plant No.	Room Vol. Cu. Ft.	Rate of Ventilation Air Changes per Hr.	Vapor Concentration	
			Breathing Zone p.p.m.	General Room Air p.p.m.
6B	2,500	5	500	290
15D	6,000	10	290	230
10B	4,000	23	500	100
13D	2,000	Natural, strong	340	80
18D	8,000	23	400	20
19D	8,000	50	60	0

trichlorethylene vapor was zero in the general room air while in the breathing zone of the operator the maximum concentration did not exceed 150 p.p.m. The solvent losses reported for the 4 tanks were 1.0, 3.0, 4.5 and 5.3 gal. per sq. ft. per 100 hrs. operation respectively. The location of one of these tanks is shown in Figure III.

In contrast to the results reported above, the vapor concentration in smaller rooms was found to be high, even in the general air, except when

adequate ventilation was provided. The data presented in Table I indicate that all tanks located in confined spaces should be safeguarded by means of general ventilation at a rate of 30 air changes per hr. It is to be observed, however, that general ventilation alone is not enough to control the exposure directly at the breathing level of the operator, and local exhaust ventilation may be required in addition. When used in conjunction with local exhaust ventilation the rate of general ventila-

FIGURE IV—Tank located in confined room

tion can probably be reduced below 30 air changes per hr.

The location of a degreasing tank in a confined space does not necessarily mean a separate closed room. Location in a pocket off a large room as in Figure IV, or in a pit below floor level, gives the same undesirable results. In one case of a tank placed in a small extension to a room 120,000 cu. ft. in volume, the vapor concentration around the tank averaged 340 p.p.m. with a maximum of 1,080 p.p.m. Pit locations should be particularly avoided because of the high density of the vapor which causes it to collect at low points. All pits containing storage tanks, pumps, or other appurtenances to degreasing equipment should be provided with positive ventilation.

DRAFTS

The tank location must also be selected to avoid disturbing drafts created by open windows and doors, fans, etc., since the action of such drafts is to drag vapor out of the tank and disperse it in the room. In this connection, the location of the tank must be carefully considered in relation to paint spray booths which are commonly operated in conjunction with degreasing equipment. Spray booths require high rates of ventilation, and strong air currents are thus established in the immediate neighborhood. In one plant the opening of the doors was found to create a strong draft by the tank which was corrected by erecting an entrance vestibule. Drafts may be created by the general ventilating system. To prevent this air inlets should be located near the ceiling, remote from the tank, and provided with upward deflectors, while outlets should be placed near the floor since the heavy vapor tends to gather at low points.

A gas heated degreasing tank with natural draft ventilation of the combustion chamber should not be located

in a room in which a mechanical exhaust system is installed unless ample free opening is provided for the intake of make-up air for the exhaust system. Otherwise a negative pressure might develop in the room which would cause a reversal in the direction of air flow through the natural draft vent pipe and thus bring the flue gases into the room. These gases may include not only the toxic products of gas combustion but also phosgene resulting from the pyrolysis of trichlorethylene. The escape of trichlorethylene vapor into a room in which welding and similar high-temperature operations are going on also presents a potential phosgene hazard and must be avoided.

TANK VENTILATION

The present study reveals that a degreasing tank of adequate design and capacity located in a large room free from disturbing drafts and properly operated with respect to thermal balance, cleanliness of solvent, and speed of operation does not create an exposure to trichlorethylene vapor in excess of 150 p.p.m. as the data in Table II show. Ideal conditions are not always found, however, since the results depend to a large extent upon the personal factor in operation. Thus in contrast to the favorable results shown in Table II we have other data indicating unsatisfactory vapor concentrations in spite of good locations, ample room volume, and excellence of tank design. Because there can be little control over the personal factor we believe that the added safeguard obtained through local tank ventilation is necessary for the safe operation of degreasing tanks except under the most favorable conditions. Specifically, it is recommended that local exhaust ventilation be provided whenever the degreasing tank is located in a room less than 20,000 cu. ft. in volume and also on tanks in larger rooms where there is

danger of drafts, high-speed operation and poor supervision.

EXHAUST VENTILATING CAPACITY

The exhaust ventilation should be applied laterally at the edges of the tank since the heavy vapor tends to roll over the edge and fall to the floor. A ventilating rate of 60 c.f.m. per ft. of tank perimeter has been found to be adequate. This produces an air movement of approximately 20 f.p.m. toward the exhaust openings at a distance of one foot from the slot. The application of ventilation to the tank disturbs the vapor zone in the tank somewhat and increases the solvent loss. This loss obviously increases with slot velocity. Moreover, it is known that the efficiency of control by lateral ventilation at a given total rate of air flow decreases with an increase in slot velocity.³ Hence, it is desirable to keep this velocity at a low figure. At the same time, the slot velocity must be high enough to make the entrance loss substantially greater than the internal loss in the section of duct into which the slot opens so as to provide for uniform air flow over the tank area and into the

exhaust system. An entrance velocity of 500 f.p.m. appears to be the minimum practical value. Typical exhaust systems are shown in Figure V and Figure VI.

FIGURE V—Local exhaust ventilation applied to degreasing tank (diagrammatic)

RECOMMENDATIONS

As a result of this study of degreasing equipment and the survey of present conditions under which such equipment is installed and operated, we desire to make the following recommendations:

FIGURE VI—Degreasing tank provided with local exhaust ventilation

I. Design of Equipment:

- A. Avoid the use of tanks and appurtenances other than of standard manufacture to insure proper design with respect to required balance between heat input, cooling capacity and thermostatic control.
- B. In every case provide a tank large enough to permit the complete immersion in the solvent of all parts to be handled and wherever possible use an enclosed tank with automatic feed.
- C. Provide a free-board distance from the maximum vapor level to the lip of the tank of not less than 15".
- D. Provide a cleanout door for the removal of sludge.
- E. Provide thermostatic control of the heating and condensing zones and in addition provide safety thermostats to limit the solvent temperature and vapor height.
- F. For gas heated tanks, install a flue from the combustion chamber to the outside of adequate capacity and equipped with a proper diverter. The flue should be of acid-proof construction throughout its length.

II. Location of Equipment:

- A. Wherever possible, locate degreasing tanks in rooms 20,000 cu. ft. or more in volume.
- B. Avoid locations in pits below the floor level or in pockets opening off large rooms.
- C. Do not locate tanks near paint-spray booths or other similarly ventilated equipment.
- D. Eliminate all drafts in the area of the tank.
- E. Gas heated equipment provided with natural draft ventilation must not be located in a room equipped with mechanical exhaust ventilation unless adequate fresh air inlets are provided to prevent the development of a negative room pressure.
- F. Operations involving open flames, electric arc, or other sources of high heat must not be carried on near degreasing tanks.

III. Local Exhaust Ventilation:

- A. All degreasing tanks in confined rooms (less than 20,000 cu. ft.) and other installations not favorably located or properly operated must be provided

with local exhaust ventilation. General ventilation is not recommended in place of local exhaust ventilation but may be required in addition.

- B. Exhaust ventilation should be by lateral movement into slots along the edge of the tank with a ventilating rate of 60 c.f.m. per ft. of tank perimeter. The slot velocity should be approximately 500 f.p.m. and provide for uniform ventilation over the entire tank area.
- C. Provide a ventilated booth or table where necessary for the temporary holding of cleaned parts for drying or for cooling.

IV. Operation:

- A. Operate the degreasing tank in accordance with the manufacturer's instructions.

- B. Pass work through the tank at a rate of 8-12' per min.
- C. Keep the tank closed when not in use.
- D. Clean the solvent and tank at proper intervals and otherwise follow manufacturer's instructions to avoid decomposition and loss of solvent.
- E. Provide solvent vapor absorbing type of respirators to be worn during tank cleaning operations.

A Precipitative Method for the Titration of Tetanus Toxin and Antitoxin*

RAYMOND L. LIBBY AND JOHN N. ADAM

Lederle Laboratories, Inc., Pearl River, N. Y.

THE obvious advantages of an *in vitro* test for determining the unit-content of tetanus toxin, or of antitoxin, has led a number of workers to try to use the flocculation test of Ramon for this purpose. Scholtz,¹ 1924, using Ramon's procedure, reported that his results indicated that the flocculation test was far less accurate than an *in vivo* test. Abt and Erber,² 1926, titrated a series of 51 samples of antitetanic serum by means of the flocculation test and claimed 90 per cent accuracy for about two-thirds of the samples tested. In only 1 of the 51 samples tested was a double zone of flocculation observed. Kalic,³ 1928, in titrating 53 samples of tetanus serum, found two and occasionally three zones of flocculation; one showing a very rapid nonspecific flocculation over a wide area, and a second (corresponding to the animal tests), in which flocculation occurs much more slowly and in a comparatively narrow zone. Hoen and Tschertkow,⁴ 1929, using a precipitative ring-test for evaluating antitetanic sera, obtained values that

corresponded to the *in vivo* results. Gosh and Ray,⁵ 1937, reported that tetanus antitoxin titrated by flocculation and *in vivo* generally agree to within about 10 per cent. Ramon, Lemetayer and Richon,⁶ 1937, utilizing the flocculative technic show that the unit-content of toxin or toxoid as determined by this method checks reasonably well with the results of the corresponding animal tests. They recommend that the flocculative test be used in preference to the animal test for determining antigenicity.

Gay, in "Agents of Disease and Host Resistance" says that, "Attempts to standardize tetanus antitoxic serum by means of flocculation have not proved satisfactory."

It would appear from a review of the literature that the greatest difficulty in titrating tetanus toxin or antitoxin is the fact that often double or multiple flocculating zones occur, only one of which represents the specific toxin-antitoxic reaction.

This report presents a rapid precipitative method for the titration of tetanus toxin, toxoid, or antitoxin. Essentially, the method consists in mixing a constant volume of toxin with decreasing volumes of antitoxin, incubating for 30 minutes in a water bath,

* Read before the Laboratory Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 28, 1938.

and determining the degree of turbidity by means of the photonreflectometer.⁷ The mixture giving the maximal reading corresponds to the neutral point and is the tube in which flocculation first appears if allowed to incubate for several hours at 45° C.

METHODS

In practice 2 cc. of toxin are mixed with decreasing volumes of antitoxin, diluted with 0.85 per cent salt solution so that it contains approximately 600–800 units per cc., the mixture is incubated in a 45° C. water bath for 30 minutes, and then the degree of turbidity is determined by means of the photonreflectometer.⁷ It is shown in Table IV that the mixture showing the maximal turbidity, as indicated by the maximal galvanometric reading, corresponds approximately to the neutral point. Thus, if one utilizes an antitoxin of known unitage, it is possible to calculate the L_t units of an unknown toxin or vice versa. For example, if the mixture of 0.2 cc. of a serum containing 800 units per cc. with 2 cc. of a toxin gives the maximal galvanometric reading, then the L_t units of the toxin equals 800×0.2 or 80 L_t units.

$$\frac{\quad}{2}$$

EXPERIMENTAL DATA

1. *Typical photonreflectometric readings obtained with mixtures of tetanus toxin or toxoid and antitoxin*—Table I shows a typical series of readings obtained with mixtures of toxin and antitoxin after 30 minutes' incubation at 45° C. As indicated, the galvanometric readings increase up to a maximum with decreasing volumes of antitetanic serum and then decrease with a further decrease in the volume of serum in the mixture. Frequently, with larger volumes of serum than those shown in the table, a very rapid nonspecific precipitation occurs, so that in this zone the galvanometric readings will go off the scale in approximately 5 minutes. Because of the rapidity and degree of precipitation occurring in this zone, it is impossible to confuse it with the much slower specific toxin-antitoxic reaction.
2. *Constancy of the combining proportions of toxin and antitoxin*—Table II shows that the mixture of 2.0 cc. of toxin number 641B and 0.4 cc. of antitoxic serum number 6901 gave the maximum galvanometric reading after a 30 minute incubation period at 45° C. If one dilutes the above mentioned toxin 1:2 and mixes it with varying volumes of the same antitoxic serum, it can be

seen from the table that only half as much antitoxin, or 0.2 cc., is required to give the maximal reading. Similarly, if the antitoxic serum is diluted 1:2 and mixed with undiluted toxin, 0.8 cc., or twice as much antitoxin, is required to give the maximal reading. These data would indicate therefore, that using the mixture giving the maximal galvanometric reading in a series of toxin-antitoxic mixtures one may calculate either units of toxin or units of antitoxin in an unknown sample if standardized antitoxin or toxin respectively is utilized.

and 0.16 cc. of antitoxic serum number 6901 gave the maximal reading regardless of the time interval. It is also shown that this same tube corresponds to the mixture that gives the most rapid and voluminous flocculation if allowed to incubate for a considerably longer time at 45° C. In routine titrations, an arbitrary incubation period of 30 minutes at 45° C. has been adopted because, as is well known, considerable variation in both the flocculation and precipitation time occurs between different samples of toxin or toxoid and various samples of antitoxic serum. In

4. *Correlation between contents of antitoxic units determined by the precipitative method and those determined by animal tests*—Table IV shows such a comparison. As shown, the mean value of the ratio of the unit-contents determined by animal test to those determined by the precipitative method is 1.022 with a standard deviation of ± 0.052 . This indicates that a reasonable degree of correlation exists between the two tests and that in general one may expect the two titrations to check within 7 per cent. This agrees with the findings of Abt and Erber in 1926, and Gosh and Ray in 1937, using a flocculative technic.

DISCUSSION

From the data given it appears that the precipitative technic outlined for the titration of tetanus toxin or antitoxin offers a rapid, quantitative method for the estimation of toxic or antitoxic

titers; however, it should be pointed out that only a limited amount of data is available at present and that more samples should be tested before final conclusions are drawn. For example, there appears to be a difference in the combining proportions of refined and concentrated antitoxin with a standardized toxin and unrefined antitoxic serum with the same toxin. Data concerning this problem will be given in a subsequent report.

Health Problems in Packing Crustacean Products*

JOHN T. R. NICKERSON, PH.D., GERALD A. FITZGERALD

Birds Eye Laboratories, Boston, Mass.;

AND

RICHARD MESSER, F.A.P.H.A.

*Bureau of Sanitary Engineering, State Department of Health,
Richmond, Va.*

THE nature of crustacean food products is such that they are usually placed at the disposal of the consumer after they have been cooked. They may be canned, in which case they are ordinarily sterilized, but often are sold freshly cooked or cooked and frozen. In those cases where unsterilized, cooked crustacean products are prepared for the consumer's use, care must be taken to eliminate and to prevent the entrance of bacteria which might be detrimental to health. The federal government has long maintained a watchful interest in shellfish and crustacean products in interstate commerce and for the most part the state governments in those areas where food plants of this type are to be found have coöperated with the federal government by the application of sanitary control measures. It is, however, the packer's problem to enforce the proper sanitary measures, since in most cases the state government is not able to supervise the operation at all times. Yet his product

must satisfy the health requirements of the U. S. Food and Drug Administration when it enters interstate commerce.

Research and control experiments, carried out in connection with the preparation of frozen, cooked crustacean products have brought out certain facts which, it is believed, might be of interest to the industry in general.

METHODS OF CONTROLLING CONTAMINATION

Cooking—It is the practice in those states neighboring the Chesapeake Bay to "pressure-cook" crabs. In other states crabs are often cooked by the older method of boiling. Lobsters and shrimps are more often cooked by boiling although there is no reason why pressure cooking is not applicable to these products.

When pressure cooking is properly carried out the packer can be sure that all fecal or related microorganisms have been eliminated. Pressure cooking offers the further advantage of a more uniform product in flavor and texture.

Many plant managers overlook the fact that the pressure cooker offers an excellent means of sterilizing equip-

* Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 28, 1938.

ment. Pans, knives, baskets, etc., can be quickly and efficiently sterilized in a pressure cooker at the start of the day's work and at the noon recess, thus helping to prevent contamination of the product with microörganisms.

In the New England States lobsters are generally cooked in a salt water solution for 10 to 15 minutes, the time depending on the size of the lobsters. Although this method of processing lobsters produces an edible and palatable food, experiments carried out on lobsters known to be polluted have indicated that viable fecal organisms are not eliminated from the gills and intestinal tract by this treatment in the short periods used commercially. In fact, with lobsters of medium size it was found necessary to boil as long as 29 minutes to remove all fecal organisms from the intestinal tract. Since lobsters are sometimes stored in polluted waters, the significance of the foregoing from a health standpoint is obvious. On the other hand, the long cooking which toughens the flesh is reduced to a minimum in pressure cooking and a superior as well as more healthful product results.

Chlorine Treatments (external in vitro)—Chlorine solutions are often used in food plants for the purpose of eliminating organisms which, if present in the finished product, might tend to cause decomposition or result in a food material unsuitable from the standpoint of public health. Chlorine, in weak solutions, is sometimes applied to food products themselves but is more often used as a germicide to remove organisms from utensils or other apparatus which might come in contact with the product.

If chlorine solutions are to be applied to crustacean products which are to be frozen, a certain amount of care must be exercised. In high concentrations (above 10 p.p.m.) chlorine may cause chemical changes in foods while they are held frozen in storage, and thus

decrease their storage life to only a few months. These changes result in a deterioration of both color and flavor. This is especially true in the case of crustacean meats.

Chlorine Treatment (internal in vivo)—Dilute chlorine solutions have long been utilized for the purification of shellfish. Two types of treatment are used. In the State of Massachusetts¹ it has been the custom to condition clams in sea water containing a residual of from 0.3 to 0.5 p.p.m. of chlorine. This concentration of chlorine is maintained throughout the treatment. In England² and at the State Shellfish Demonstration Plant at Willoughby, Norfolk, Va.,⁴ a slightly different method is used. Shellfish are given a short preliminary treatment with sea water containing a relatively large proportion of chlorine (up to 5 p.p.m.), after which they are held for longer periods in sea water, previously chlorinated to remove fecal organisms, but containing no chlorine.

It is the claim of those adherents of the type of purification used in England that the oyster or clam is purified and cleaned by its own biological and physiological activity, rather than by chlorine in the water used during treatment. Thus, if the available water is sterile, shellfish will clean themselves, provided other environmental factors are suitable. Since chlorine irritates molluscs, causing them to cease drinking, conditions are said to be more suitable for purification when this substance is absent from the sea water used. Chlorine is used with the English method primarily to eliminate fecal organisms from the treatment water before it is used to condition the molluscs.

With both procedures the time of the conditioning process varies with the degree of purification required, the relative pollution of the shellfish at the start, the temperature of the treatment water, etc.

While clams and oysters are often removed from polluted areas and given purification treatment before they are placed on the market, the authors are not aware that this method is employed commercially for crustaceans. It is nevertheless true that both crabs and lobsters are sometimes floated in water known to contain numerous fecal organisms.

VALUE OF CHLORINE IN SANITARY CONTROL OF CRUSTACEAN PACK- ING OPERATIONS

Chlorine solutions are of considerable assistance in the maintenance of sanitary plant conditions provided they are utilized in an intelligent manner. It is of little use to use chlorine on utensils that are covered with organic matter, since the chlorine is removed from solution by such material. It is, therefore, necessary to clean utensils and apparatus before using chlorine because the mere use of a chlorine solution by itself will not suffice.

It should not be expected that the use of chlorine solutions on crustacean products themselves will solve all sanitary problems. Since such substances are organic in nature they remove chlorine from solution. If, therefore, chlorine is to be used there must not be an accumulation of organic waste material in the wash water, for a stage will finally be reached at which chlorine is removed faster than it can be added. Even though there is no accumulation of waste organic matter chlorine must be constantly supplied to such wash water for the reason that it tends to combine slowly with the product. It is probable that the most suitable method of using chlorine in wash water for crustacean meats is to maintain a constant flow of water containing a definite amount of available chlorine. For all practical purposes, this can be easily arranged by setting up a constant flow of water through a tank containing

a small, valveless outlet, a solution of sodium hypochlorite, or other suitable chlorine source, being allowed to drip slowly from an aspirator bottle into the stream of the incoming water. The amount of chlorine used can be regulated by screw clamp and rubber hose, so that the concentration of this substance in the wash water remains approximately constant for any given flow.

If a food material contains fecal organisms it is hardly possible to remove them by treatment with ordinary chlorine solutions. It has been found that lobster meat containing fecal organisms can be soaked in water containing 10 p.p.m. of chlorine for as long as 2 minutes without destroying all *Escherichia coli* in the product. A concentration of 10 p.p.m. of chlorine was maintained throughout the 2 minute interval; moreover, the lobster meat had been contaminated externally with the bacteria.

Although undesirable organisms are not always removed from shellfish meats by treatment with chlorine it is often quite desirable to use this agent in wash water when packing crustacean products. This is especially true in the case of lobsters where it is necessary to wash tail meat to remove liver particles. The chlorinated wash serves to maintain a low bacterial population in the water, thereby preventing the inoculation of the product with bacteria.

CONTROL OF PACKING OPERATIONS

During the preparation of crustacean products, to be sold as fresh frozen, it is necessary to maintain a constant vigilance with respect to sanitary measures. Whether the product be crabs, shrimps, or lobsters, the proper procedures are much the same. Sanitary type utensils are helpful and often necessary. In this connection utensils, tables, etc., made from stainless steel or an equally non-corrosive material are efficacious since such implements are very easy to clean. Zinc, and galvanized

iron while often utilized to cover tables used in the packing of crustacean products are not desirable for several reasons. An oxide tends to collect on equipment covered with these metals which promotes the accumulation of dirt and makes cleaning and sterilizing difficult. Moreover, these metals wear out quickly leaving holes which are often left unpatched, and hence become traps for waste materials. Even when such worn places are patched the resulting cover is not desirable since dirt-collecting ridges are unavoidable.

The elimination of flies is another problem which must be dealt with by the packer. In one case in which a shrimp product was found to contain *Escherichia coli* it became necessary to peel the shrimps before cooking, cook them in screened trays, cool in the cooking trays, and screen the packing line. Flies were found to be the source of contamination, and since it was impossible to eliminate all flies from the plant itself the above precautions were required.

One of the most important features of packing crustacean products is the training of the workers, a feature which is often overlooked. It is useless to attempt to eliminate the coliform group from a food material if the workers are to handle contaminated articles and then handle the product without properly cleansing their hands. Although state and federal authorities issue statements summarizing sanitary procedures which, if followed, would assure the elimination of fecal organisms, many pertinent points may be easily neglected by a large number of packers unless the utmost control is exercised.

PURIFICATION EXPERIMENTS ON CRUSTACEA (*the blue Crab—Callinectes sapidus*)

The blue crabs taken from the Chesapeake Bay area often come from polluted water localities. In order to elim-

inate fecal organisms, therefore, packing plants in this vicinity usually employ pressure retorts for cooking crabs. A pressure of from 13 to 15 lbs. for 15 to 20 minutes is used. Since the time is taken at the moment that the steam is turned on, the actual pressure-time period cannot be stated. The load in the retort, the efficiency of exhaustion, the temperature of the crabs entering the retort, and other factors determine the temperature-time period of the cook.

The composition of crustacean muscle is such that it is toughened when cooked for long periods. This toughening persists or may even increase after such products are frozen, as storage at temperatures below freezing continues. Provided the cooking of crustacean meats is not too severe, there is little toughening of the product after freezing and during storage.

It seemed, therefore, that a better product might result provided the cooking time was shorter. Moreover, it might be possible to obtain a greater yield by shortening the processing time. Since the long cooking is necessary to destroy organisms which might be detrimental to health it would become necessary to remove them by some other method if the time of cooking were shortened. Conditioning or purification treatment appeared to be the only suitable method by which to remove fecal organisms prior to processing.

THE PURIFICATION STATION

The research concerned with the purification of the blue crab was carried out at the State Shellfish Demonstration Plant at Willoughby, Norfolk, Va. This plant is a two story frame structure 21 ft. by 25 ft. in plan and 18 ft. high.

The treatment tanks, installed on the first floor, were wooden and similar to those designed by Dodgson at Conway, England.² The small treatment tank used was 4 ft. long, 2 ft. wide, and 3 ft. deep, and constructed of cypress lum-

ber 0.15 ft. thick. A baffle was located at each end of the tank and a penstock gate at the inlet end facilitated cleaning of the floor. The floor of the tank contained a false grated bottom and had a slope of 1:50 toward the outlet end.

The water storage tank was also located on the first floor. This tank held 1,400 gallons and contained a mixing baffle at each end. Carborundum air diffusers were located near the outlet end. The sea water, pumped from Hampton Roads through a 2½ in. suction line, first entered a mixing baffle where the chlorine solution, used to remove fecal organisms from the water, was added. The amount of chlorine solution entering the tank could be regulated through a graduated valve on the container in which it was held. The mixing baffle in the outlet end of the storage tank could be used for adding thiosulfate to neutralize chlorine if desired. Aeration of the water was accomplished through the carborundum diffusers in the outlet end of the tank. A pump room, located on the first floor, contained a single unit by means of which water and air were pumped to the storage tank.

EXPERIMENTAL PROCEDURES

The crabs used in purification experiments were obtained from the Chesapeake Bay in areas known to be polluted.

The size of the treatment tank was such that only a small number of crabs

(21 to 81) were used for each test. The storage tank was first filled with sea water, enough chlorine being added to allow a residual of approximately 0.5 p.p.m. immediately after filling operations were completed. The residual chlorine dissipated in a period of ½ hr. while, at the rate that water was allowed to flow through the treatment tank, about 3½ hrs. were usually required to empty the storage tank.

The crabs were given an initial washing with salt water and placed in the treatment tank. At this time 3 crabs were removed for laboratory test. In some cases crabs were placed on racks, in the normal position, but usually were free to swim about in the tank. Water from the storage tank was then allowed to flow into the treatment tank until filled, after which inlet and outlet valves were so regulated that the water level remained approximately constant. With the loss of head in the storage tank the speed of water flow was lessened; it was therefore necessary to regulate the flow at the inlet valve from time to time. The water was aerated periodically, about 6.5 p.p.m. of dissolved oxygen being present at all times. When the storage tank was nearly empty it was again pumped full, chlorine being added as previously. The

treatment tank, therefore, was filled with water throughout the experiment.

After the treatment period had been completed 3 crabs were removed and

examined in the laboratory. In making tests for fecal organisms the gills were removed from the crabs and combined. They were then cut up into small pieces

and 10 gm. were placed in 100 cc. of sterile dilution water. Ten cc., 1 cc. and 1/10 cc. portions of the dilution water (in using untreated crabs higher dilutions were used) were placed in lactose broth and incubated at 37°C. for 48 hrs. Confirmations were made on eosin-methylene blue agar. The same procedure was used for the gizzard-like proventriculus or pharynx and intestines of the crabs, excepting that when intestines were used it was not possible to obtain 10 gm. of the original material. In such cases the results obtained are based on the number of fecal organisms in 100 cc. of dilution water containing intestines of 3 crabs.

During the purification experiments the temperature of the treatment water was taken at hourly intervals. The number of crabs which failed to survive purification treatment was recorded in each case.

In determining the oxygen requirements of crabs (Table I) a number of these Crustacea were placed in the treatment tank and the tank was filled with sea water. Dissolved oxygen determinations were made on the water in the tank at the start of the experiment and at 15 minute intervals thereafter for a period of 1 hr.

EXPERIMENTAL DATA

The water used contained approximately 6.6 p.p.m. of dissolved oxygen per gallon. For purposes of calculation 6.6 p.p.m. can be considered as 24.95 mg. of dissolved oxygen per gallon. The number of gallons of water per hour required to keep the dissolved oxygen of the water constant during the purification treatment can, therefore, be determined.

In Table III the Most Probable Number of coliform organisms³ are given as per 100 cc. of the original dilution water or per 10 gm. of gills or 10 gm. of gizzards. For intestines the figures represent the Most Probable

Number of coliform organisms per 100 cc. of dilution water containing three intestines or per three intestines.

DISCUSSION

It is apparent that crabs require much more oxygen than oysters in order to carry out their physiological processes. According to Messer and Reece⁴ oysters consume an average of 35 to 128 mg. of dissolved oxygen per bushel per hr. at temperatures ranging from 21.3°C. to 23.7°C. At somewhat higher temperatures (25.0°C. to 29.25°C.) crabs have been found to require from 240.10 to 271.16 mg. of dissolved oxygen per dozen per hr. A direct comparison between these two aquatic specimens cannot be made. However, it is evident that one bushel of crabs would consume much more oxygen than the same volume of oysters under identical conditions. This has a significant practical aspect since in practice a volume of sea water two or three times greater would be necessary for the treatment of crabs than that required for the purification of the same volume of oysters.

Unlike the oyster, the crab continues to pump water through its gill chambers even in the presence of 5 p.p.m. of chlorine. This has been demonstrated by placing colored solutions close to the water intake area of crabs (branchial clefts) held just under the surface of water containing 5 p.p.m. of chlorine. The colored solutions could be seen to flow from the water outlet clefts near the mouth.

The mortality rate of crabs during treatment was high, an average of 13.7 per cent. While there is no direct evidence that such is the case it is believed that the condition of the crabs when they arrived at the treatment station and the high temperature of the water during treatment were partly responsible for the high mortality rate. Chlorine, in the concentration used, appears to have no detrimental effect. The fact

that lobsters are floated commercially under similar conditions of pollution would indicate that such methods might be employed for other species of Crustacea.

The results of the purification experiments indicate that only rarely are all fecal organisms removed from the gills, pharynx, and intestines of grossly polluted crabs during treatment. On the other hand, a relatively large reduction of coliform organisms was obtained in almost every instance. It would appear to be more difficult to remove fecal organisms from gills than from the pharynx and intestines of crabs taken from areas known to be polluted. A factor which may be of significance in this respect is the fact that the contents of the pharynx and intestines are usually absorbed or excreted during the treatment period. The gills, on the other hand, often contain considerable sand and detritus even after a purification period of 48 hours duration.

It would be difficult to predict the commercial practicability of crab purification. Provided the temperature and time of cooking could be so decreased as a result of purification treatment to provide a sufficiently superior product and a sufficiently great increase in yield to offset the cost of purification, the process would be justified. It is believed, nevertheless, that in Massachusetts and in Canada where for commercial reasons other than purification it is the practice to float lobsters (*Homarus americanus*) the use of water containing a small residual of chlorine or previously treated with chlorine would have obviously beneficial effects. Lobsters are generally cooked in a weak saline solution. Ordinarily the cooking times and temperatures used are not sufficient to remove fecal organisms from lobsters when these organisms are present. Instead of floating lobsters in sea water containing fecal organisms, as is some-

times done, chlorine in small amounts might be added with little cost. This is especially true in those cases where lobsters are held in tanks containing salt water or sea water.

SUMMARY AND CONCLUSIONS

It is ordinarily not possible to remove all coliform organisms from crabs (*callinectes sapidus*) taken from polluted areas, by holding them in sea water containing no fecal organisms for periods of 24 to 48 hrs. duration. However, a very large percentage of the fecal organisms present in such crabs are removed during treatment.

Due to the fact that crabs require large amounts of oxygen, considerable quantities of sea water must be supplied during the purification treatment of such Crustacea.

A relatively large proportion of crabs died during the purification treatments. This is believed to be due to a combination of the high temperature of the water available and the condition of the crabs when they arrived at the State of Virginia experimental purification station.

A practical aspect would be the use of the purification method to reduce the boiling time for both crabs and lobsters where for any reason pressure cookers are not used.

One must realize, however, that once the crustacean meats are sterilized, unbelievably strict precautions must be exercised to prevent their recontamination.

The National Health Program

*How Far? How Fast?**

ABEL WOLMAN, DR.ENG., F.A.P.H.A.

President, American Public Health Association, Professor of Sanitary Engineering, Johns Hopkins University, Baltimore, Md.

BEFORE attempting prophecy in any field it is important to define the character and limits of the area in which one is to do the crystal gazing. What is the national health program about which so much has been said and published within the past year? Even at the risk of repetition it is desirable to summarize briefly its outstanding features so as to avoid argument upon issues and facts not included therein. So much of the controversy about the national health program is concerned with problems only remotely related to it, although these collateral issues may have important social and political significance in other directions.

For purposes of the present discussion the following general assumptions appear non-debatable:

1. The health of the people is a matter of public concern.
2. Ill health is a major cause of suffering, economic loss, and dependency.
3. Good health is essential to the security and progress of the nation.

These assumptions appear to be axiomatic. If controversy rages around any one of the three it can only be because there is difference of opinion regarding the machinery necessary to correct the deficiencies. Certainly at

this date no reasonable opposition may properly be raised to the three fundamental tenets stated above. Upon them rest the basic recommendations in the national health program confirmed in the general agreement reached at the National Health Conference in July, 1938. At that conference no one contested the fact that serious needs for medical service were unsupplied and that society had failed to make full application of available medical science to prevent or control disease and disability.

No one fails, of course, to derive great satisfaction from the increase in the average length of life in our country and from the improvement in the average levels of health and well-being. As the President of the United States has indicated, however, in his message to the Congress of January 23, 1939: "These improvements in the average are cold comfort to the millions of our people whose security in health and survival is still as limited as was that of the nation as a whole fifty years ago."

THE NEED

Statistical evidence of unfulfilled national health needs could be quoted here at length and perhaps even *ad nauseam*, because every published document has emphasized and re-

* Presented at the Thirty-seventh Annual Meeting of the New York Tuberculosis and Health Association, Hotel Pennsylvania, New York, N. Y., March 2, 1939.

emphasized in overwhelmingly convincing statistical data that essential resources for the prevention and care of sickness are lacking in many rural areas and are grossly inadequate in many smaller cities; that hospital services for persons with low incomes are insufficient in many cities; that, at the same time, hospital beds in private and semi-private rooms stand empty because patients are unable to pay the private rates, even in such tremendously wealthy cities as New York City; that in rural areas, general hospital and clinic services are either insufficient or wholly lacking; that government hospitals for tuberculosis and mental diseases are generally overcrowded and inadequately supported.

The statistical evidence would furthermore demonstrate, without reasonable contradiction, that among other specific ailments, tuberculosis, pneumonia, cancer, malaria, mental and nervous disorders, industrial injuries, and occupational diseases are far more prevalent or more deadly than they need to be.

We might go on to prove with more figures that maternity, infancy, and childhood are very inadequately protected, especially in rural areas, and that between one-half and two-thirds of maternal deaths, nearly one-half of stillbirths, and between one-third and one-half of the deaths among new-born infants are preventable. While we are seeking methods for prevention, largely administrative and financial in character, more than 70,000 lives a year are lost in this area of health service delinquency. These lives could be saved.

If your skepticism required further piling of statistical Ossa on Pelion, you should be reminded that on an average day of the year about 5 million persons are disabled by sickness and that about half of them remain permanently disabled. During the course of an average year sickness and disability cost the

American people nearly 2 billion days' absence from work, school, or household duties. Those in the labor market lose annually by this sickness and disability over a billion dollars in unearned wages.

It may be reasonably concluded that the need for a national health program is clear. The history of health service in the United States shows with equal clarity that no rigid lines can be drawn between the services required for the prevention of disease and those essential for the care of the sick. In defining the objective of a national health program, therefore, one must assume that all areas in the country and all members of the population shall have the protection of adequate public health services and an opportunity to avail themselves, in accordance with their medical needs, of adequate care in sickness.

THE NATIONAL HEALTH PROGRAM

Paraphrasing the findings of the report on national health by the Interdepartmental Committee, one might say that in the United States we have patients without doctors, hospitals, and public health service; and doctors, hospitals, and public health service without patients. What is the program for correction? In its simplest terms it rests primarily upon the recommendations of the Interdepartmental Committee, discussed and confirmed at the National Health Conference held in Washington, D. C., July 18-20, 1938. These specific recommendations may be restated briefly as follows:

a. The expansion and strengthening of existing federal-state coöperative health programs under the Social Security Act, through more nearly adequate grants-in-aid to the states, and, through the states, to the localities.

If this recommendation were put into effect, it would require, at its peak, additional annual expenditures by fed-

eral, state, and local governments, of \$365,000,000, or somewhat less than one cent per capita per day.

b. Grants-in-aid to the states for the construction, enlargement, and modernization of hospitals and related facilities where these are nonexistent or inadequate but are needed, including the construction of health and diagnostic centers in areas, especially rural or sparsely populated, inaccessible to hospitals. Grants toward operating costs during the first years of such newly developed institutions to assist the states and localities in taking over responsibilities.

Averaged over a 10 year period, the total annual cost of such a program, including special 3 year grants for maintenance of new institutions, is estimated at \$147,400,000, or approximately 0.3 cent per capita per day.

c. Grants-in-aid to the states by the federal government to assist them in developing programs of medical care.

It is estimated that this part of the program could begin with the expenditure of \$50,000,000 the first year with gradual expansion until the expenditure reaches the estimated level of \$400,000,000 annually which would be needed to provide minimum care to the medically needy groups. At the peak this would involve approximately somewhat less than one cent per capita per day.

The maximum annual cost to federal, state, and local governments to implement financially recommendations (a), (b), and (c) is estimated at about \$850,000,000 at the full level of operation within a 10 year period. In the 10th year, therefore, the average per capita per day cost for the people of the United States for the National Health Program would be less than 2 cents.

An additional recommendation made by the Interdepartmental Committee transcends perhaps in ultimate im-

portance the three already noted. The committee, in making the recommendation, directs attention to the economic burden created by sickness for self-supporting persons. The committee emphasizes particularly that the costs of sickness are burdensome more because they fall unexpectedly and unevenly than because they are large in the aggregate for the nation or, on the average, for the individual family. The burdens of sickness costs can be greatly reduced through appropriate devices to distribute these costs among groups of people and over periods of time. In this particular field everyone is aware that the approach to the objective must be made slowly. Planning for a program of medical care sufficiently widespread to serve 130 million people would obviously require some years of development. It is probable that both public funds and private insurance contributions will ultimately find major places in the basic development of this particular undertaking. Here, too, the committee is in agreement with most observers that the rôle of the federal government should be principally that of giving financial and technical aid to the states in their own development of sound programs through machinery and financial plans largely of their own choice.

HOW FAR—HOW FAST?

The rate of implementing such a program as briefly outlined above rests, as Thomas Parran has recently pointed out, largely upon our future social concepts of which public health action is an integral part. Haggard has similarly suggested that "The physician fails to see that medicine itself is one of the institutions affected by the changes that are brought about (by medical science). Medicine does not stand alone; it is an integral part of society. . . . Public opinion determines the condition and future of medicine. . . .

"The permanent basis of medicine is not its research, but its social application—its practice."

The speed with which the national health program is converted into action is contingent therefore upon how rapidly its objectives become clear to and are accepted by the lay and professional members of society. For the moment all of us are so concerned with the machinery of implementation that we have lost sight of the tremendous social sweep involved in the proposals. How far and how fast the program should move rests almost entirely with the desires of the people. Many misguided individuals have the belief that the program will rise or fall upon the support of opposition of this or that group of official or voluntary professionals. This is highly unlikely, because, in this as in every other important step forward in social progress, the public has dragged the professional groups with it in its march toward attaining the wider benefits of medical and public health service. The history of public health development in this country and in England discloses many confirmatory evidences of the fact that major steps forward in public assumption of responsibility for the prevention and cure of disease have generally resulted because of the demands of the people, in spite of the lethargy and meticulous attention to detail of the professional worker.

The question which now confronts your own and every other interested group in this country is whether or not we shall repeat the errors of lack of courage, of procrastination, and of resistance to sound and logical public demand which have marked the steps forward in every other country as well as in our own.

No one can escape the fact that the development of such a program as outlined is beset with dozens of administrative, financial, and psychological

problems. These may be attacked and solved with timidity or with courage. Upon the nature of this attack will depend the answers as to how far and how fast the country may proceed.

The satisfactory development of the program will require the expenditure of large amounts of money, but it is money which is now spent in too great part inadequately, wastefully, and unintelligently. An essential of this program as in any other preventive program is the provision of adequate funds for research into the cause and cure of disease. To maintain the quality, scope, and amount of medical service essential for the successful operation of the program will place great strains upon the facilities for the education of physicians and other professional persons. Professional workers in the public health field will be needed in increasing numbers. Time must be permitted for their training and for their absorption into the administrative activities which will confront us in the future.

Notwithstanding these pressing and difficult problems, the need for correction should control the decision as to the speed of adoption of answers. We have always found a way to provide the machinery for improving the general level of health of our people as the necessities were demonstrated and as the scientific facts warranted. A prime requisite, however, for a successful search is a universal recognition of need. This universal recognition is still delayed.

A RISK AT PROPHECY

In reviewing these problems, one is always tempted to indulge in the dangerous art of prophecy, even while remembering Lowell's dictum in *The Biglow Papers*: "Don't never prophesy—onless ye know." The speaker hazards the following comments, however, assuming a high de-

gree of indulgence on the part of the audience.

1. Within 10 years the major elements of the national health program will be in effect, because the people want it, can pay for it, and are entitled to it.

2. The public health officer will play a major rôle in the evolution of the program, not always because he wants it, but because the forces of logic normally place the responsibility upon him.

3. Medical care will be universalized for the medically needy and for the lower income groups. It is probable that this universalization will proceed through the channels of tax-supported subsidies and voluntary insurance programs and ultimately toward a compulsory insurance scheme. This approach through experimental operations

to compulsory health insurance will probably consume several decades, because in this as in all other efforts toward social amelioration, we must experience the same mistakes made elsewhere, before we learn to avoid them. These mistakes, contrary to the views of many, have considerable constructive value since they result in processes adjusted to the peculiarities of our own people and institutions.

4. In the fields of medical care and public health, equalization or levelling of necessary service independent of geography or economic status will occur as it has in universal education, postal service, transportation, public welfare, and other basic necessities for a safe and healthy society of people. Resistance to universalizing these services is doomed to fail as long as we preserve a true faith in democratic institutions.

Preliminary Observations on the Epidemiology of Mental Disease*

A. W. FREEMAN, M.D., F.A.P.H.A., AND
BERNARD M. COHEN, PH.D.

The Johns Hopkins University, Baltimore, Md.

THE application of the epidemiologic method to the study of diseases other than those caused by infectious agents has often been suggested. Some attempts have, in fact, been made to put these suggestions into practice but most of these attempts have been based on broad statistical studies rather than detailed investigations in the field. They have not been markedly fruitful.

The social and economic implications of the problem of mental disease are so tremendous and the limitations of study by the usual clinical methods are so strict, that an attempt to study the prevalence of mental disease in the field by the epidemiologic method seemed justifiable.

The Eastern Health District of Baltimore offers a favorable field for such a study. Its population of some 57,000 has been carefully studied over some 7 years, and unusually complete and detailed information as to its composition and characteristics is available. The presence within the district of a large psychiatric clinic with its active outpatient department, makes available a psychiatric service of the highest order, and the well organized health activities of the district maintain con-

tinuous and intimate contact with the population.

The study of mental disease in the district, made possible by a grant from the International Health Division of the Rockefeller Foundation, has been in progress for some 4 years. The fundamental purpose of the work is to study the prevalence of mental deviation in the field, by the methods usually spoken of as epidemiologic; that is, by a study of the cases with a view to isolating such differences as they may exhibit when compared with the population as a whole.

The difficulties have, of course, been considerable. No precedents are to be found in the literature for such a study, and technics have had to be worked out as the study progressed. Since the work covered both the work of psychiatry on the one hand, and of epidemiologic statistics on the other, personnel capable of working in the two fields had to be developed.

The object of the study, mental deviation in its broad sense, is by no means well defined either clinically or otherwise, and no reliable statistics are at present to be found other than those based on admissions to mental hospitals or to mental hygiene clinics. The first step was, naturally, to attempt to determine the true rates of prevalence of mental deviation, as a whole

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 27, 1938.

and by types, for the year 1933. This involved the collection of all available information regarding every discoverable case of frank psychosis which had been committed to a mental hospital or treated in a clinic, or otherwise come to attention, and regarding all persons who had in any manner exhibited recognizable evidence of mental deviation.

While this initial census cannot be regarded as complete, it brought together the names of, roughly, 3,900 persons who could be regarded as coming within the general scope of the study. This is 7 per cent of the total population of the district. In this gross total of 3,900 cases, were included about 1,300 adult delinquents of whom nothing is known other than the fact that they were arrested by the police for a wide variety of offences. Eliminating these from the total, there remained about 2,500 people, or $4\frac{1}{2}$ per cent of the population, who seem proper objects of study.

The collection, tabulation, and analysis of the material regarding these 2,500 people have proved difficult and time consuming procedures. The cases have been classified by the psychiatric member of the staff according to broad "reaction types." Of these broad classifications, analysis of the cases of psychosis and of personality deviations is sufficiently advanced to give some idea, at least quantitatively, of the problem.

In the class of the psychotics are found 335 persons, a rate of 818 per 100,000 of the population 15 years of age and over. The white rate (875) is considerably in excess of that for Negroes (599). These figures represent the total number of residents of the district who were in 1933 to be classified as "psychotic."

First admissions correspond roughly with the incidence rates in other diseases. For 1933, this included 71 cases, or a rate of 175 per 100,000

population per annum. In first admissions the Negro rate is considerably higher than that of the white, 252 against 155, and the rate for males of both races is markedly higher (214) than that for females (139).

One striking fact is the marked difference in the incidence of psychosis between the two wards of the district. The two wards do not differ greatly in character or in the general composition of the population. Considering total prevalence, Ward 6, which occupies the southern half of the district, has a rate of 969 per 100,000 as against 679 for Ward 7. This difference holds for both whites and Negroes. The number of first admissions is so small for a single year that reliable detailed incidence rates cannot be calculated until the experience of a number of years is available.

The larger group of cases classified as general personality disorder, permits of more detailed analysis than does the relatively small group of psychotics. Such an analysis of this material, including 1,310 cases, has revealed many interesting and perhaps significant facts. Here again the southern ward (6) exhibits a far higher rate of prevalence than does the northern ward (7). The eastern sections of both wards show far higher rates than do the western. While a large part of this difference is due to the distribution of the Negro population, which is for the most part concentrated in the western end of the district, this factor does not explain all of the difference. In general, the rate of prevalence for the white population tends definitely to vary directly with the proportion of the Negro population living in the same area.

An interesting factor in the situation is presented by the Jewish population, which constitutes, roughly, slightly more than 9 per cent of the white population of the area. The Jews of the Eastern Health District present far

PERSONALITY DISORDER

*Rates of Prevalence per 1,000 of Population for the Eastern Health District,
By Color, Race, and Geographic Division*

Race	Rates per 1,000 Population					
	Ward Six			Ward Seven		
	East	West	Total	East	West	Total
Whites:						
Jews	35.74	64.07	47.96	19.23	53.36	40.52
Non-Jews	16.16	27.37	17.68	10.40	13.16	10.77
Total White	18.90	43.52	23.64	10.52	18.63	11.76
Negroes	28.27	21.69
Total		36.46			20.82	

higher rates of personality deviation than do the remainder of the white population, and a large part of the difference in prevalence in the white population as between the two wards is due to concentration of Jews in Ward 6. This does not, however, account for all the differences, since the rate of prevalence in non-jews in Ward 6 is significantly higher than in Ward 7. The rate of prevalence of Jews in both wards is from three to four times as high as that of non-Jews. Similarly significant differences in rates of prevalence are exhibited when the two wards are divided into eastern and western sections. Both for Jews and non-Jews, the rates in the western sections are higher than those of the eastern.

Analysis has been made by size of household, showing significant increase in prevalence in both wards with increase in the size of the household. Analysis by economic status shows extraordinary differences. In Ward 6, homes of the lowest economic status

have rates almost 6 times as high as do homes of the best classes, and the difference in Ward 7 is almost as great.

Even such simple analyses of the basic data as have been outlined, those of color, sex, race, geographic distribution and economic status, reveal important and sometimes striking differences in the prevalence within the district of certain forms of mental deviation. Of the significance of these differences, it is as yet too early even to speculate. The work already done indicates only that at the time of the first census these differences did exist. Subsequent work will show whether or not they are constant, and may make their interpretation possible.

Along with the analysis of the material collected for the year 1933, current information has been accumulated, and for the year 1936 a second census has been made. The analysis of this material should, when completed, answer some of the questions raised by the material here presented.

Integration of Health Department Records*

MARJORIE T. BELLOWS, F.A.P.H.A., AND
GEORGE H. RAMSEY, M.D., F.A.P.H.A.

*Statistician, and Commissioner, Westchester County Department
of Health, White Plains, N. Y.*

DURING the first 6 years of its existence the Westchester County Department of Health accumulated more than 500,000 partially or fully completed medical and nursing record forms. Of these, approximately 175,000 were primary records, the remainder being duplicates, special summary forms, and index cards.

This heterogeneous mass of records was kept without reference to integration and according to the general scheme of having separate files for each unit of the department and for each specific service rendered. Thus, if the divisions of tuberculosis and nursing needed the same data regarding a case, the original record form was filed with the tuberculosis division and in addition a duplicate was made and filed with the division of public health nursing. Originals and duplicates in each division were generally filed according to residence of the individual they referred to. When some other method of classification seemed desirable, new sets of duplicates, or summary forms were made. Nearly every file had its own cross-index, separate and distinct from other

similar indices. No one individual was responsible for devising forms, instructing field personnel as to filling them out, supervising files, or for the mechanical details of analyzing records collected. Each division director independently managed his own record system and directed the efforts of clerks assigned to him.

This uncontrolled hit or miss development led both to administrative difficulties and to inefficient service. The situation arose where nurses were spending as much as a quarter of their time making out and copying record forms. This proportion increased according to the whims and desires of division directors for additional information and the subsequent installation of more and more record forms. Records pertaining to a given individual could not be assembled from the department's numerous files without undue labor and expenditure of time, if at all. Correlated analysis and study of services rendered was virtually impossible.

Since conditions similar to these in Westchester County probably exist elsewhere, a progress report of efforts to develop a more efficient record keeping system is appropriate. Such a report is given in this paper, and is preceded by a brief description of the

* Read before the Vital Statistics Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 25, 1938.

organization of the Westchester County Department of Health.

This department serves a population of 314,000, so distributed as to present widely varying problems. Most of the southern half of the district is suburban to New York City and is essentially metropolitan in character, while the northern half is sparsely populated and rural. The central office is located in White Plains, a city of 42,000. Under the Commissioner are two deputy commissioners. The department is organized in the following divisions—communicable disease, sanitation, tuberculosis, pediatrics, public health nursing, syphilis, and statistics.

Although the work is for the most part administered from headquarters, clinic and nursing services are decentralized. The 24 field nurses work out of four district centers, each of which is directed by a supervising nurse and staffed with clerical personnel. Within each district are from six to eight substations. Some of these are used only for clinic sessions, and others both for clinics and the holding of office hours by nurses.

The director of the statistical division has been given general supervision of the majority of headquarters and field records, excepting those of the division of sanitation. The content of record forms and the kind of information desired are decided upon in coöperation with the various administrators and specialists concerned. However, the statistical division is alone responsible for the manner in which data are obtained, and made available for routine use or special analysis.

Three fundamental record units have been established in accordance with the organization scheme of the department. The field unit comprises files of active family folders kept in the four district offices. The headquarters unit is a series of case registers, one for each medical service. The third unit is an

essential correlating agency—a single master index located in the central office. This index cross files alphabetically all other files of the department and shows where each record for a specific individual may be located. Field records are moved after each use to the central office where clerks enter appropriate information in the case registers and index before returning them to field offices. A detailed description of each of these record units follows.

FAMILY FOLDER FILES

The family folder has been selected as the most logical and flexible unit for field files. There is a series of alphabetical files of family folders in the district nursing centers, one for each sub-center included in the district area. This single unit replaces and consolidates a former file of nursing records arranged by families, and files of medical records, arranged first by services and by individual within service. The new family folder contains the following records.

1. A family history to be used by medical and nursing services
2. Medical and clinic records for members of the household
3. Records of nurses' home visits

Incorporated in the social history sheet are a household roster and a service summary. The household roster shows for each individual, name, date of birth, sex, color, relation to head of household, date of entrance into the household, occupation, and a general description of health status. The service summary lists the members of the household carried at any time on active clinic or home visiting lists, the specific services rendered with date of admission and space for date of discharge and reason.

Medical records, so far as possible, conform schematically to one pattern in order that whoever uses them may know

the approximate location on the form of the information desired. The face sheet for each medical service contains identifying information, a medical history, and the findings of the first examination. Its reverse side and the second sheets are simple continuation forms. There is a minimum of duplication on the medical records of information already given on the social data sheet.

A form for noting the results of nurses' home visits is in experimental use. Nursing record forms in common use have been abandoned and in their place has been substituted a ruled sheet with a column at the left for a date and the name of the person to whom the notes refer. The nursing record thus becomes a chronological narrative for the entire household roughly indexed by date and individuals. Such a form is made possible by keeping histories in the same folder.

To facilitate handling what in some instances is a rather large volume of records, a special type of folder is being installed with attachments for holding records in place, as well as separate sub-divisions for segregating the various classes of records. The filing edge of the folder bears a label showing the name of the head of the household and address. Labels banded with a color, each color representing a single service, serve as signals for household counts. Figures on the labels indicating the number of individuals receiving that service are signals to be used in individual counts.

Records for discharged cases are removed from the family folder and kept in a central discharge file for the entire health district, but the fact that an individual in the household has been discharged from a service is noted on the service summary.

The folder is taken by the nurse into the field when she is making home visits; it is used by the physicians and

nurses in clinics. The folder is sent to headquarters after a clinic visit for necessary interpretation of new data by physicians and for register entry and indexing by clerks. It is held there no longer than 24 or 48 hours before being returned to the field. After a nursing visit, the folder is given to the clerks in the district offices who forward necessary data to the central office for register entry and tabulation.

The advantages gained from this type of field record are these: The number of forms in use has been reduced by at least one-third. As far as possible, records serving the same general functions have the same form and follow the same field and office routine. There is little or no duplication of information on the different types of field records. The field worker, doctor, or nurse writes one and only one set of observations concerning a case. These observations are available without copying or summarizing to other persons who need them.

CASE REGISTERS

Case registers are sets of files in the headquarters office designed to serve two functions. They are used by division directors and others for case reference and are the source of data for routine reports and special studies. Formerly files of duplicate field records served the first of these purposes, and a set of summary records were used for the second. The case registration card is an expansion of the summary form to include data required for case reference. These data, however, are entered in coded or abbreviated form. As a result the card is small enough to be manipulated easily in tabulation, and the information is in suitable form for statistical classification. Visible files of 4 x 6" cards with significant facts coded on the filing edge have proved very useful in adapting reference files to statistical use.

A series of case registers, one for each health department activity, is maintained in the central office. The individual card shows the type of observation required, the care, treatment, and follow-up service given by members of the department staff, and the results of such service together with significant dates. There are separate case rosters for each clinic service (tuberculosis, syphilis, infant and child hygiene, orthopedics, etc.), and each registers all persons who are or should be receiving care or observation from that service. The files of birth and death certificates, reported cases of communicable diseases, and a file showing the immunity status of preschool children with respect to the more important acute communicable diseases, are case rosters essentially since they register individuals who require certain types of health department supervision. By filing with them additional data regarding follow-up service, they become similar in content and function to other case registers.

In general, direct reports to the health department are noted in the registers before being passed on to the field representatives concerned and, conversely, field records after each use are sent through them for entry of new data by clerks. They are, therefore, always up to date. They impose no clerical work on field personnel. Correlated medical and nursing data are available for health appraisal, and can be amplified for special studies without creating additional field forms or disturbing the routine of field records.

MASTER INDEX

With the wide diversity and constant flow of records, it is essential to establish an integrating agency to locate all forms pertaining to a given individual, indicate where entries of new information should be made, and facilitate transfers from one file to another. The

agency selected for the Westchester County system is a master index with a card for each individual who has permanent records on file. The card shows, in addition to identifying information, the exact location of the records relating to the individual. The index cross-files registers (including birth and death certificates), active and inactive files of field records, and other miscellaneous files of the department, such as X-ray films and laboratory reports. Each record is checked with this file before being used in any other office or field procedure. The use of symbols to indicate types of records makes it possible to use a small card. A visible soundex file, such as the one installed in Westchester County where 85,000 individuals are indexed, decreases greatly the time required in looking for names.

The index has already proved to be extremely valuable in a number of ways. Other files may be arranged in some way except alphabetically when desirable. The clerical staff can locate quickly the records requiring entries of new information. It acts as an automatic device for coördinating information on file, and, therefore, substitutes one checking operation for many. For example, death certificates are checked with registers of tuberculosis and syphilis cases, with birth certificates and nurses' active cases in one simple operation. It serves as a clearing agency for changes of address, a very important function in a county such as Westchester where the rate of migration is very high.

The maintenance of this record system does not require a larger clerical force than did the original unplanned one. The transfer from the old to the new system has, of course, necessitated additional temporary clerical personnel, and 8 clerks were supplied through a WPA project for an 18 month period. Now the force is practically the same

as under the old system and is producing better data and giving better service than previously. In all fairness, however, it should be pointed out that the deficiencies of a poor system increase geometrically with the number of records involved. Possibly small county health units may not waste as much time and effort through bad record practices as does a large unit like that in Westchester County. If this is true, suitable modifications in the system might be made in applying it to small organizations.

SUMMARY

The record plan described herein emerged after considerable trial and error, from attempts to decrease the amount of record work required of field personnel, and to put data already

accumulated in such form that they could be located and used. It has these salient characteristics: The household is recognized as the primary unit of field service and a household folder of records is designated as the place to record basic data. The folder is kept permanently in the hands of the persons who use it most, namely the field personnel. Movement of the primary record to persons who require it replaces numerous special report forms and duplicates filled out by field personnel. One set of secondary records for reference and analysis, kept at headquarters and handled by trained clerks, takes the place of office duplicates and statistical summary cards. An integrating and correlating agency is created through which all new data must pass before they are permanently filed.

Industrial Medical Department Organization*

JOHN J. PRENDERGAST, M.D., F.A.C.S.

Medical Director, Chrysler Corporation, Detroit, Mich.

RECENTLY, considerable attention has been directed toward industrial medical organizations in large corporations. Industrial corporations employing approximately 25,000 workers or more have designed medical departments well staffed with physicians, nurses, and technicians, which have sponsored the development of industrial hygiene laboratories and have developed integrated coöperation with numerous other departments usually found in large scale industrial operations such as safety engineering, plant engineering, material specifications, group insurance, legal and compensation departments.

While this progress has been very logical and commendable, it is significant that of all this nation's workers, relatively few are benefitted by such large medical organizations. In fact, 99.5 per cent of all of the industries employ less than 1,000 workers each, and 98.6 per cent have less than 500 workers. Out of 8,838,743 so employed, only 2,159,989 are to be found working in larger establishments employing over 1,000 men. This leaves 6,678,754 workers in the smaller establishments. These figures were taken from the federal census material of

1930, and are limited to establishments reporting annual products valued at \$5,000 or more.

The medical organization of a large industrial corporation can and should be very complete. In such a department, the medical director is a thoroughly qualified physician having complete authority and control over all medical activities of the organization. The department includes physicians qualified in traumatic surgery and industrial medicine, ably assisted by a staff of industrial nurses, clerks, and ambulance drivers.

These industrial nurses ordinarily should be limited in their functions to the treatment of minor abrasions, lacerations, contusions, and other minor miscellaneous injuries. The nurse also undertakes certain treatments, does some of the redressings, and at times clerical work. All of her work is under the direct supervision of a full-time physician. For duty during the night hours, male nurses are often preferred in certain cases.

Available to these physicians and closely correlated with their work, there should be an industrial hygiene laboratory capable of routine analyses and field surveys relating to industrial health hazards and leading to the elimination or control of such hazards. It is necessary for such an industrial hygiene

* Read at a Joint Session of the Industrial Hygiene and Public Health Nursing Sections of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 28, 1938.

laboratory to be organized on the basis of properly qualified personnel including such physicians, chemists, and engineers as may be necessary to deal with the particular health hazards in any given corporation. Where such problems exist, the laboratory must be prepared to employ methods for sampling and analyzing various dusts, smokes, fumes, vapors, mists, or irritating substances. The industrial hygiene laboratory also maintains an adequate reference library; it is interested in toxicological problems, and must have contacts with local public health agencies. The industrial hygiene laboratory must be in a position to observe its corporation's compliance with public health rules and laws.

Complete coordination between the medical department and the employment department, production supervision, group insurance, safety engineering, plant engineering, and plant management, is indispensable.

However, it has been indicated already that a significant majority of the nation's workers do not fall into the classification of large scale industrial employment. This majority is employed by thousands of small manufacturers. How, then, is a complete medical service such as outlined possible to this large group of workers?

Most of these smaller plants do not operate on a sufficiently large scale to warrant the employment of a full-time physician. For some it would not appear possible to employ the full-time services of an industrial nurse. In the face of this apparent difficulty, it is none the less true that herein lies the greatest opportunity for the nurse of today who is interested in industrial nursing.

Present opportunities in industrial nursing can best be explained by discussing the qualifications of an industrial nurse, including special capabilities necessary for industrial nursing in con-

trast to other forms of nursing, and certain other qualifications which will enable her to adapt herself to the particular needs of manufacturers employing labor on a small scale.

Naturally, certain attributes such as neatness, character, and pleasing personality, along with academic attainments such as graduation from the best type of nursing school, are essential. Innate enthusiasm and interest in workers of all classes are no less important in small industries than in large plants. In the smallest industrial units, where there is no provision for attendance by a physician, the industrial nurse must be able to assume certain additional responsibilities. She should also have that rare ability to carry out certain administrative functions in a friendly manner, yet ever maintaining the dignity of her profession.

The industrial nurse must have more than these admirable qualities to fit into a small scale industry. She must be able to understand problems of management and supervision as well as those of wage earners, and in some instances act as an adviser in promoting mutual understanding between these groups. Her position in this aspect of promoting a fine employee-employer relationship is unique indeed.

While it is usually recognized that all industrial nurses are carrying out at least a type of public health nursing, the nurse in a small plant, where physicians are not employed, has an even greater need of ability in public health problems. She must be familiar with local laws and rules pertaining to public health problems and should understand the entire local program of public health agencies.

In addition to having part-time medical service, or perhaps no regular medical service, the smaller industrial unit seldom has any industrial hygiene laboratory facilities unless such are

provided by an insurance carrier. Even in the latter case the industrial hygiene coverage is prone to be scant. Therefore, it is necessary for the industrial nurse of this type to familiarize herself with many of the rudiments of that science which is now called "industrial hygiene."

Industrial hygiene perhaps partakes of the engineering, chemical, and medical professions, but is rapidly being recognized as an entity apart from these professions. It is not visualized that the average industrial nurse of this type will become an expert industrial hygienist. It is hoped that the nurse will recognize her limitations in this field and seek proper consultation in the same manner as she has been taught to do in cases of illness or injury. However, where the volume of nursing and actual first aid work is small, she must necessarily sell herself to her prospective employer on the basis of added functions, and this is one of them.

Ordinarily, any plant, however small, lists among its manufacturing operations several potential sources of occupational disease. These should be appraised and studied in particular so that the nurse may advise the management or supervision in regard to the common health problems of her plant.

In the initial appraisal of health hazards in any particular plant, it is hoped that she may be aided by some form of industrial hygiene coverage such as that furnished by many insurance carriers. This may serve to designate the outstanding health problems sufficiently so that the nurse may develop more detailed knowledge regarding these few hazards by directed reading in the literature, and contacts with physicians and scientific meetings. In Michigan last year there was formed a new society known as the Michigan Society of Industrial Hygiene whose membership is open to all persons interested in or doing any phase of indus-

trial hygiene. Particular attention is given to the problems of those doing work in smaller plants.

In many of the smaller industrial units the combined work embraced under the titles "first aid" and "industrial hygiene" may not be sufficient to warrant the employment of full-time nursing service. Therefore, in order that the nursing profession may fill this potential professional market more successfully, it should whenever possible present other qualifications such as stenography, filing, and kindred office work.

One finds it interesting to note the number of nurses who now are supplementing their professional abilities with studies in stenography and various other office routines to make themselves more valuable office assistants to physicians. Nurses who have this training can make themselves invaluable to smaller industries in the dual rôle of nurse and office worker; and, depending on their ability, can handle the personnel work for these plants in a very satisfactory manner; also, in some cases, they may increase the value of their services, where the volume of work already indicated is sufficiently small, by various other types of nursing—visiting services or social services where mutual aid or mutual insurance societies exist.

When the establishment of a medical department in a small plant is contemplated, and it is planned to utilize the services of the type of industrial nurse described herein, one initial step is advisable. In all these instances, the plant management or the insurance carrier usually has selected a nearby physician for reference in cases of compensable diseases and injuries. The nurse should consult freely with this physician and elicit his aid in the establishment of standing orders and routine treatments.

Now, it will readily be seen that, should any of these activities individ-

ually consume very much time, such a scope as outlined would be impossible. But in the smallest types of industrial units, it is preferable and will lead to greater efficiency when the industrial nurse recognizes all of the possible ramifications of her position so that she may be better prepared and better

qualified in each of these aspects rather than allowing them to be handled in a haphazard manner as problems in these different classifications arise.

Proper study and training directed along these lines will certainly help industrial nurses to make a place for themselves in small industries.

Relationship of Doctor and Patient

THE profession of medicine is one of the most individualistic of all professions. The relationship between doctor and patient is a highly individual relationship, with something of a religious character, even though the doctor has long ceased to be actually a member of the priesthood as he was in earlier times. In a country such as ours it is a very good working rule—and indeed it is more than that: it is a fundamental principle—that individual enterprise should not be interfered with by the State unless that enterprise is either injurious to others or to the community, or is failing to deliver the goods or services which the community requires. I think this principle is generally observed in the relations between the general practitioner and the State. The State or municipality can lend organizing power, and it can supplement the work of the individual by

making available facilities which the individual could not provide for himself or by creating conditions in which the individual can make a more effective contribution to the common good. But the State is not, as is sometimes supposed, a bureaucratic machine trying to bring everything under its control because of a blind worship of the Unknown God of tidiness, and, although it is sometimes accused of adding every year to the number of things in Acts of Parliament which are subject to the approval of the Minister of Health, much of the time and energy of Ministers and their Departments is in fact spent in resisting the acceptance of such control or jurisdiction because it is clear that the public interest, which must be paramount, does not require it.—Health and the State, Walter Elliot, *Brit.M.J.*, Feb. 25, 1939, p. 4077.

Practical Procedures and Limitations in Present-Day Smoke Abatement*

H. B. MELLER, Sc.D.

*Chief, Bureau of Smoke Regulation, Department of Public Health,
Pittsburgh, Pa.*

NO individual was more closely in touch with smoke abatement problems than the late O. P. Hood, who was chief mechanical engineer of the U. S. Bureau of Mines; and no one had a better understanding of the difficulties involved. Asked why smoke abatement efforts do not bring more satisfactory results, he once said:

The main reason is an incorrect estimate of the kind and size of the job. When an industrial community realizes that keeping the air clean is a project of similar magnitude to keeping streets clean, providing clean water, removing city waste, or guarding the moral atmosphere, then there may be a real hope of success. We usually think of the project in too small terms. It is thought of as the dog catcher or the boiler inspector—a matter of a man or two, a job or two, a small appropriation of variable and uncertain amount, to be abolished in a fit of economy and reestablished under pressure of a vigorous minority. Even so, it is surprising how much is obtained for the effort; but the community is rarely satisfied, for the job is bigger than it was conceived to be . . .

This is a clear statement with which I believe all engaged actively in smoke abatement enforcement will agree. Misconception of the magnitude of the problem is reflected in governing ordinances and budgets which are mainly responsible for today's limitations.

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-seventh Annual Meeting in Kansas City, Mo., October 27, 1938.

THE ANTI-SMOKE ORDINANCE

Most of the anti-smoke laws now in effect are the outgrowth of ordinances written twenty or more years ago, when fuel-burning equipment was less efficient from the standpoint of smoke abatement, and when processed fuels were not as common as now, and when we knew a lot less about the subject in general.

These outmoded ordinances were prepared in the light of conditions that since have improved in many respects, not the least of which is the change in the spirit of antagonism toward regulation.

Now, as then, atmospheric contaminants come from many sources, but in an urban atmosphere, are mostly products of fuel combustion. Products of combustion are solid, liquid, or gaseous; some are visible to the eye and some are not. The visible was tangible, so the finger of accusation was levelled at "visible smoke." If it could be suppressed, it was thought the cause of general complaint would be removed. But it appeared that, for one good reason or another, it would be too drastic to prohibit the emission of all visible smoke in a soft coal burning community. Thus it was agreed that the prohibition should not extend beyond "dense" smoke—smoke that is opaque as it leaves the stack.

But, again, it was felt that this would be too severe, so it was decided that dense smoke should be permitted for a specified limited period. No time limit was placed on "light" smoke. Cinders, ash, and sulfur gases were not mentioned—not because they were unrecognized as objectionable, but because at that time control was considered impracticable. Private dwellings and small apartment houses were made exempt as inviting too much trouble under the conditions then existing; in other words, regulation covered considerably less than 10 per cent of the total number of stacks in the city.

There you have the limits of the ordinance of ten or twenty years ago. How do they compare with those in effect today?

The *Manual of Ordinances and Requirements*, published in August of this year by the Smoke Prevention Association, analyzes ordinances of 77 cities in the United States and 3 in Canada, ranging in population from 37,000 to 7,434,000. One city is listed as permitting no dense smoke; 16 apparently limit the emission of dense smoke to periods of cleaning or building new fires (cleaning fires is a time-worn excuse); the remainder allow certain other specified periods of dense smoke. And some of the later ordinances include regulation of private homes and small apartment houses, apparently on the same basis as industrial and commercial plants.

Some progress, therefore, would seem to have been made—at least on paper. But the plant operator still can say, if he wishes, "Catch me." And further, firemen could, if they would, cause a tremendous aggregate of smoke of "permissible density." Fortunately they are not so inclined.

THE ENFORCEMENT STAFF

Since knowledge of conditions still is

dependent upon observations by smoke inspectors—in other words, direct reading and timing—the number of violations recorded will be proportional to the number of inspectors or observers. Forty-five of the 80 cities included in the report made by the Smoke Prevention Association have no full-time employees on smoke abatement. Most of them list one or more part-time—boiler inspectors or sanitary inspectors. Nineteen more have only one man. In the larger cities, while there are more full-time employees, the ratio of employees to population is low. For example, in Hudson County, N. J., and in St. Louis, Mo., the ratio is 1 to 66,000 persons; in Chicago, Ill., it is 1 to 80,000; in Washington, D. C., it is 1 to 105,000; and in Pittsburgh, Pa., the ratio is 1 to 175,000.

THE BUDGET
